till Sept. 23d; during which time, the sun being north of the equator, shines more directly upon this part of the earth, which renders this the hottest period of the year. The entire year is also sometimes divided into summer and winter, the former signifying the warmer and the latter the colder part of the year. —Indian summer, in the U. **SUN**, *n.* [*Sax. sunna; G. sonne; Sans. sunuh.* The Danish has *Sunday*, Sunday, Slav. *Sonze*. Qu. W. *tan*, Ir. *teine*, fire, and *shan*, in *Bethshan* | 1. The splendid orb or luminary which, being in or near the centre of our system of worlds, gives light and heat to all the planets, and is therefore the primary cause of all the motions and changes effected on the surface of our globe by those mighty agents. The light of the sun constitutes the day, and the darkness which proceeds from its absence, or the shade of the earth, constitutes the night; Ps. cxxxvi. All the planets and comets of our system revolve round the sun as a common centre, at different distances and in different periods of time. His mean apparent diameter is about 32 minutes, and his mean distance from the earth about 95,000,000 of miles. His real diameter is 882,000 miles, and hence his magnitude is

1,384,472 times that of the earth, but his mass or quantity of matter is only about 28 times that of the earth. He revolves on his axis from west to east in 25½ of our mean solar days, his axis being inclined at an angle of 82° 40' to the plane of the ecliptic. When viewed through powerful telescopes the sun's disc is observed to have frequently large and perfectly black spots upon it. These spots are of various irregular shapes, and of various sizes, from the least visible to the twentieth part of the sun in diameter. They alter in size and gradually vanish, lasting from a few days to six or seven weeks. Herschel conjectures that the shining matter of the sun consists of a mass of phosphoric clouds, floating above his atmosphere, or else mixed with the higher strata of it, and that owing to disturbances in the equilibrium of this luminous atmosphere, openings are made through it; and that therefore a spot on the sun is a portion of the body of the sun itself, seen through one of these openings. Several hypotheses have been advanced respecting the emission of heat and light from the sun, but none of them are satisfactory. The sun, besides his motion round his own axis, revolves round the common centre of gravity of the solar system, which centre is a point within the body of the sun. The apparent diurnal motion of the sun from east to west, is owing to the revolution of the earth on its axis, and his apparent annual path in the ecliptic from west to east, is owing to the motion of the earth round the sun in an elliptical orbit, the sun being in one of the foci. Astronomers seem to have ascertained beyond a doubt that the sun has a proper motion in space, and is advancing along with the planets toward some distant point among the fixed stars. —2. In *popular usage*, a sunny place; a place where the beams of the sun fall; as, to stand in the *sun*, that is, to stand where the direct rays of the sun fall. —3. The right of the superior is technically called *dominium directum*, and the interest which the vassal enjoys in the land is called *dominium utile*, and also fee or property. By the law of Scotland, the sovereign is overlord or superior of all the lands in the kingdom; but a person holding lands under the sovereign as superior may convey them to another, to be held under himself as superior; and in general a proprietor of land may convey the same to be held under himself as superior.

Thus if iron has more specific gravity than water, it will sink in that fluid; and the floating of iron on water must be a *supernatural* event. Now no human being can alter a law of nature; the floating of iron on water therefore must be caused by divine power specially exerted to suspend, in this instance, a law of nature. Hence, *supernatural* events or miracles can be produced only by the immediate agency of divine power.

**SUPERNATURALISM**, *n.* The state of being supernatural. — 2. A term used chiefly in German theology, in contradistinction to *rationalism*. Also, the two salts of sulphuric acid and potassa are called *sulphate* and *bisulphate*, the first containing an equivalent of the acid and alkali, and the second two equivalents of the acid and one of the alkali.

**SUPERSEDEAS**, *n.* In *law*, a writ of *supersedeas* is a writ or command to

suspend the powers of an officer in certain cases, or to stay proceedings; as, to stay an execution after a writ of error has been allowed, and bail put in; to set aside erroneous judicial processes, &c. In bankruptcy, it is the writ used for the purpose of superseding the fiat. It respects God and beings superior to man, and extends to our religious opinions, worship, and practices. It displays itself in excessive exactness or rigour in religious opinions or practices; extreme and unnecessary scruples in the observance of religious rites not commanded, or of points of minor importance; excess or extravagance in religion; the doing of things not required by God, or abstaining from things not forbidden; or the belief of what is absurd, or belief without evidence. We apply the word *superstition* to the idolatry of the heathens; we apply it also to the Jews, who made the will of God of no effect by their traditions, and substituted ceremonies in place of the religion of their fathers. It is applied to the unscriptural opinions, rites, and ceremonies of the Roman Catholics; and to those protestants who esteem baptism and the Lord's Supper, and the punctual observance of other ceremonies, without regard to morality, as sufficient to ensure salvation. Those persons are also reckoned superstitious who believe, without any evidence, that prophecies are still uttered by divine inspiration, and that miracles are still performed. The word is also extended to those who believe in witchcraft, magic, and apparitions, or that the divine will is declared by omens, or augury; that the fortune of individuals can be affected by things indifferent, by things deemed lucky or unlucky, or that diseases can be cured by words, charms, or incantations.—2. It arises fleshy from the whole of the base of the scapula that is above its spine, and likewise from the spine itself, and from the superior costa. Its principal use seems to be to assist in raising the arm upwards; at the same time, by drawing the capsular ligament upwards, it prevents it from being pinched between the head of the os humeri and that of the scapula.

**SUPRAVULGAR**, *a.* [*supra* and *vulgar*.] Being above the vulgar or common people.

**SUPREMACY**, *n.* [*See* SUPREME.] State of being supreme or in the highest station of power; highest authority or power; as, the *supremacy* of the king of Great Britain; or the *supremacy* of parliament. The term, however, is used particularly to signify supreme and undivided authority in ecclesiastical affairs. This is either papal or regal. Papal supremacy is the authority, legislative, judicial, and executive, which the pope exercised over the churches of England, Scotland, and Ireland, until the middle of the 16th

## SURBASED

century, when it was abolished, and which he still exercises, *de facto*, over that portion of the inhabitants of those countries who are in communion with the church of Rome. Regal supremacy is the authority and jurisdiction which the king of England exercises over the church of England, as being the supreme head of that church. This authority is not legislative, but judicial and executive only. Henry VIII. was first acknowledged supreme head of the church in 1528; and this supremacy was confirmed by parliament to him, his heirs, and successors, kings of this realm in 1534. Regal supremacy over the church is not recognized by the established church of Scotland, as it acknowledges no head upon earth.—*Oath of supremacy.* In Great Britain, an oath which renounces or abjures the supremacy of the pope in ecclesiastical or temporal affairs in this realm. It is, properly speaking, an oath of non-supremacy, since it negatives the pope's supremacy, and is silent as to any supremacy of the king. It was by many statutes required to be taken, along with the oath of allegiance, by persons in order to qualify themselves for office, &c.; but it is now become almost an unmeaning form.

**SUPREME**, *a.* [*L. supremus*, from *supra*; *Fr. suprême.*] 1. Highest in authority; holding the highest place in government or power. The parliament of Great Britain is *supreme* in legislation; but the king is *supreme* in the administration of the government. His commands are *supreme*, and binding on all his creatures.—2. Highest, greatest, or most excellent; as *supreme* love; *supreme* glory; *supreme* degree.—3. **SURD**, *a.* [*L. surdus*, deaf.] 1. Deaf; not having the sense of hearing.—2. Unheard.—3. Designating a quantity whose root cannot be exactly expressed in numbers.

**SURD**, *n.* In *alge.*, an irrational quantity; a quantity which is incommensurable to unity. Or, a *surd* denotes the root of any quantity, when that quantity is not a complete power of the dimension required by the index of the root. Hence, the roots of such quantities cannot be expressed by rational numbers. Thus the square root of 2, the cube root of 4, the fourth root of 7, &c., are surds, for they cannot be expressed by rational numbers. Surds are usually represented by prefixing the radical signs indicating the operation; thus,  $\sqrt{2}$ ,  $\sqrt[3]{4}$ ,  $\sqrt[4]{7}$ , or they may be expressed by fractional indexes;

thus,  $2^{\frac{1}{2}}$ ,  $4^{\frac{1}{3}}$ ,  $7^{\frac{1}{4}}$ , &c. If 2, 4, and 7 be represented by *a*, *b*, and *c*, then  $\sqrt{a}$ ,  $\sqrt[3]{b}$ , and  $\sqrt[4]{c} = a^{\frac{1}{2}}$ ,  $b^{\frac{1}{3}}$ ,  $c^{\frac{1}{4}}$  are surds. Any rational quantity may be expressed in the form of a surd by reducing its integral index to an equivalent fraction; thus,  $a^2 = a^{\frac{2}{1}}$ , or  $a^{\frac{4}{2}}$ .

**SURDITY**, *n.* Deafness.

Magistrates, and justices of the peace, have the power to take such recognizances. A magistrate or a justice of the peace may, according to his discretion, bind all those to keep the peace, who, in his presence, shall make any affray, or shall threaten to kill or beat any person, or shall contend together in hot words; and all those who shall go about with unlawful weapons, or attendance to the terror of the people; and all such persons as shall be known by him to be common barrators, and who shall be brought before him by a constable, for a breach of the peace, in the presence of such constable; and all such persons who, having been before bound to keep the peace, shall be convicted of having forfeited their recognizance. Such recognizance may be obtained by any party from another, on application to a magistrate, and stating on oath that he has just cause to fear that such other "will burn his house or do him a corporal hurt, or, that he will procure others to do him mischief." This kind of surety is termed, in Scots law, *law burrows*. Sureties may be similarly required for the good behaviour of parties who have been guilty of conduct tending to a breach of the peace.

He that is *surety* for a stranger shall smart for it; Prov. xi.

**SURF**, *n.* The swell of the sea which breaks upon the shore, or upon sand banks or rocks.—2. In *agriculture*, the bottom or conduit of a drain. [*Local*.]

**SURFACE**, *n.* [*Fr. sur*, upon, and *face*.] The exterior part of any thing that has length and breadth; one of the limits that terminates a solid; the superficies; outside; as, the *surface* of the earth; the *surface* of the sea; the *surface* of a diamond; the *surface* of the body; the *surface* of a cylinder; an even or an uneven *surface*; a smooth or rough *surface*; a spherical *surface*. In *geom.*, a surface or superficies is defined to be "that which has length and breadth only," and is thus distinguished from a line which has length only, and from a solid, which has length, breadth, and thickness. The extremities of a surface are lines, and the intersections of one surface with another are also lines. A *plane surface*, is that in which any two points being taken,

## SURGE

the straight line between them lies wholly in that surface. A surface which may be cut by a plane through any given point, so that the line of common section of the plane and surface may be a curve, is called a *curved surface*; as, the surface of a sphere, cylinder, or cone. Surfaces are distinguished algebraically by the nature and order of their equations. Thus, we have surfaces of the first order, or plane surfaces, and surfaces of the second order, or curved surfaces. Surfaces are also distinguished by their mode of generation; thus the surface of a sphere is generated by the revolution of a semicircular arc about the diameter, which remains fixed. In *physics*, a surface is supposed to be composed of a number of material particles, placed together side by side, without any opening or interstice between them. Such a surface, therefore, cannot be said to be absolutely destitute of thickness, but may be regarded as a film of matter whose thickness is indefinitely small. In *common language*, the word surface is often used to signify not merely the outside or exterior boundary of any substance, but also a certain thickness of the exterior material part. In this way we speak of the *surface* of the earth, the *surface* of the soil, of taking off the surface of any thing, &c.—*Surface damage*, in *Scots law*, damage done to the surface of the ground in consequence of mining operations, &c.

2. To slip back; as, the cable *surges*. **SURGELESS**, *a.* (sur'less.) Free from surges; smooth; calm.

**SURGEON**, *n.* (sur'jon.) [contracted from *chirurgion*.] In a limited sense, one whose profession or occupation is to cure diseases or injuries of the body by manual operation. In a more general sense, one whose occupation is to cure external diseases, whether by manual operation, or by medicines externally or internally. But this latter definition is still too limited, as there are many diseases which cannot be considered *external*, and which, according to modern practice, fall within the province of the surgeon. The truth is, no accurate definition of the term has yet been given, for the reasons stated under *surgery*,—*which see*.

**SURGEONCY**, *n.* The office of surgeon in the army or navy.

**SURGEONRY**, *† n.* The practice of a surgeon; surgery; a surgery.

**SURGERY**, *n.* Originally, the manual procedure by means of instruments or not, directed towards the repair of injury, and the cure of disease, in contradistinction to the practice of *medicine*, denoting the treatment of disease by the administration of drugs or other substances, supposed to be of a sanative tendency. The matured progress, however, of the healing art, has rendered such a definition of surgery, in these days, utterly untenable. Many attempts have been made to define surgery according to its present state, so as to prevent interference with the department of physic. By some it has been represented as that branch of medicine which principally effects the cure of diseases by the application of the hand alone, by the employment of instruments, or the use of topical remedies; but this definition is more applicable to the state of surgery some centuries ago, than to the present state of practice. By some writers surgery is said to have for its object the treatment of external diseases, while physic treats of internal diseases. This definition can only be received with numerous exceptions in regard to modern practice, for there are many internal disorders, which are universally allowed to constitute strictly surgical cases; as, for instance, the psoas abscess; stone in the bladder, polyp, and scirrhus of the uterus, stricture of the œsophagus, an extravasation of blood within the skull in consequence of accidental violence. Others have defined surgery to be the mechanical part of physic; but this definition is equally objectionable, as it confines this branch of medicine within too narrow limits. The fact is, that the line of demarcation between surgery and physic cannot be easily traced, nor is it desirable that the attempt should be made. Their principles are the same throughout, and the exercise of their different branches requires the same fundamental knowledge. The physician, before he can be accomplished or successful in his profession, must be intimate with the principles, if not with the practice, of surgery. On the other hand, no one can lay claim to the title of surgeon, far less hope for eminence or success, unless he be equally qualified to assume both the appellation

and the employment of the physician. Surgery, however, in its common acceptation, has been understood to include:

1. The treatment of injuries of all kinds; 2. Of the greater part of external and local complaints; 3. Of such internal affections as produce changes recognizable *externally*; for example, alterations of *figure*, colour, or consistency; 4. Of all cases requiring external topical treatment, operations, or manual proceedings of any kind. Still there are various exceptions to some of the above principles of classification.

The striped surmullet (*M. surmuletus*, Linn.) is somewhat smaller, but equal to the red surmullet in delicacy. [See **MULLET**.]

**SURMULOT**, *n.* A name given by Buffon to the brown or Norway rat.

**SURNAME**, *n.* [Fr. *surnom*; It. *soprannome*; Sp. *sobrenombre*; L. *super* and *nomen*.] 1. An additional name; a name or appellation added to the baptismal or Christian name, and which becomes a family name. Surnames, with us, originally designated occupation, estate, place of residence, or some particular thing or event that related to the person. Thus *William Rufus* or *red*; *Edmund Ironsides*; *Robert Smith*, or *the smith*; *William Turner*. Surnames seem to have been formed at first by adding the name of the father to that of the son, and in this manner several of our surnames were produced. Thus from *Thomas William's* son we have *Thomas Williamson*; from *John's* son we have *Johnson*, &c. Surnames are said to have been first assumed in England a little before the Conquest, but they were never fully established among the common people till the time of Edward II. They seem to have been introduced into Scotland in the time of William the Conqueror.—2. An appellation added to the original name. My surname *Coriolanus*. *Shak.*

the temporary stop of a man's right, as when a seignory, rent, or other profit out of land, by reason of the unity of possession of the seignory, rent, &c., and of the land out of which they issue, lies dormant for a time.—10. In *Scots law*, the name of a process in the supreme civil or criminal court, by which execution or diligence on a sentence or decree is stayed until the judgment of the supreme court is obtained on the point. In civil causes, the party complaining presents a bill of suspension to the lord ordinary on the bills, setting forth that diligence has been used or threatened in virtue of the decree or warrant to which he objects, and after stating the circumstances of the case, and his cause of complaint, his bill concludes that the diligence or execution in question ought to be suspended, and therefore he prays for letters of suspension in the premises, and offers caution to implement the decree of which he complains, and to pay the expenses of the process, if the court shall so decide. If the lord ordinary thinks that the complainant has made out a sufficient *prima facie* case, he pronounces an interlocutor, sisting execution in the meanwhile, and appointing the bill of suspension to be answered. Afterwards, the lord ordinary resumes consideration of the bill along with the answers (if lodged), and if he still thinks that there is ground for the objection to the diligence or execution, he passes the bill of suspension, or grants warrant for expeding letters of suspension at the signet, whereby the cause is brought formally into the court of session. If, on the other hand, the lord ordinary be of opinion, either on considering the bill itself, or on resuming consideration of it with answers, that there is no just ground of complaint, he refuses the bill, and the diligence or execution is in consequence allowed to proceed. His decision, however, is subject to the review of the court. [See BILL.]—11. In *mech.*, points of suspension, in a balance, are the points in the axis or beam where the weights are applied, or from which they are suspended.—12. In *music*, every sound of a chord to a given base, which is continued to another base, is a *suspension*.—*Suspension of arms*, in war, a short truce or cessation of operations agreed on by the commanders of the contending parties, as for burying the dead, making proposals for surrender, or for peace, &c.—*Suspension and interdict*, in *Scots law*, a judicial remedy competent in the bill chamber of the court of session, where there has been no decree, nor any proceeding which can issue in a decree, but where the object is to stop or interdict some act or to prevent some encroachment on property or possession, or in general to stay any unlawful proceeding. The remedy is applied for by a bill of suspension and interdict. [See INTERDICT.]—*Suspension and liberation*. In *Scots law*, where a debtor has been incarcerated in consequence of diligence on a decree, or on any other warrant of incarceration, he may apply in the bill chamber for redress by a bill of suspension and liberation, and if he can satisfy the lord ordinary on the bills that his imprisonment has been wrongful or illegal, the bill of suspension and liberation, after it has been answered, will be passed. The procedure in this

**SUSPENSION-BRIDGE**, *n.* A structure which is hung and stretched across some chasm, water-course, or other space, over which it is designed to form a passage. In modern structures of this sort, the leading features for the most part consist in fixing securely, in the two opposite banks, the extremities of strong chains, which, being carried over piers or pillars, reach across the space to be passed in such a manner that each portion of chain intercepted between two piers is allowed naturally to assume, by its weight, the figure of the curve named the *catenarian*. From these chains, a platform for the roadway is suspended by means of a series of equidistant vertical rods. The largest suspension bridge is that over the Menai Strait, the distance between the points of suspension being 560 feet.

powerful flier of the swallow tribe which visits this country. It has pro-

bably the most imperfect feet of any known bird. Owing to their extreme shortness, it is unable to walk, except with a most constrained and hobbling gait, and with the assistance of the wings. It lives habitually, and pursues its prey at a greater height from the ground than the swallows, and it constructs its nest at a more lofty elevation, choosing the crevices of steeples and towers, and the crannies of rocks. During the long summer days it often passes sixteen hours in vigorous continued flight. The swift is among the last of our swallows in its arrival, and the first to depart. Another species, the white-bellied or Alpine swift (*Cypselus Alpinus*, Temminck) is known in this country, but it is only a rare straggler. The weight of the swift is most disproportionately small to its extent of wing, the former being scarcely an ounce, the latter eighteen inches; the length of the body being near eight inches.—4. Their feet are placed far back on the body, attached to short and compressed tarsi, and with palmated toes. The bill is long, enabling them to search for their food below water while they swim on the surface. Their sternum is very

## SWINE

long, affording a complete guard to the greater part of their viscera, having on each side but one emargination or oval foramen filled up with membrane. Cuvier divides this order into four families. 1. The Brachypterae, comprehending the grebes, divers, guillemots, auks, and penguins. 2. The Longipennae, including the petrels, puffins, albatrosses, gulls, terns, noddies, and skimmers. 3. Totipalmatae, comprehending the pelicans, cormorants, frigate birds, boobies, and darters. 4. **SWIMMING**, *n*. The act of sustaining the body in water, and of moving in it; as fishes, which are assisted in this action by their air-bladder and fins. Amphibious animals also possess this faculty to a greater or less extent. Swimming, as applied to human beings, is the act or art of balancing the body on or near the surface of the water, and of making a progress through it. A great proportion of the animal tribes are furnished with a greater or less capacity for swimming either in water or on its surface, but man is unqualified for swimming without learning to do so as an art, owing to the structure of his body. The head by its gravity naturally sinks in water, and thus causes drowning, unless it, or at least the mouth, can be kept above the surface by art. The art of swimming, which can be acquired by exercise only, chiefly consists in keeping the head above water, and using the hands and feet as oars and helm. The best school for swimming is deep water, and the best teacher the frog. Swimming is a highly useful exercise; it strengthens the abdominal muscles, the muscles of the chest, the organs of respiration, the spine, neck, and arms. It increases courage, and furnishes an agreeable excitement. It also affords us the means of preserving our lives or those of others in perilous situations.—2. Dizziness.

is very common in Palestine, Arabia, and Egypt, growing large, and to a great height, and, though the grain is coarse, much used in building, and very durable. Its wide-spreading branches afford a grateful shade in those hot climates, and its fruit, which is produced in clustered racemes upon the trunk and the old limbs, is sweet and delicate. It bears fruit several times in the year. —*Sycamore maple*, the *Acer pseudo-platanus*, Linn., a well known large timber-tree, long naturalized in England, and much used in ornamental planting. The timber is used for certain parts of musical instruments, and various other purposes. There are several varieties. The *sycamore*, [falsely so called,] or plane tree of North America, is the *Platanus occidentalis*, Linn., commonly called button wood, or cotton tree.

**SYC'AMORE-MOTH**, *n.* A large and beautiful moth or night butterfly, so called because its caterpillar feeds on the leaves of the sycamore.

**SYCE**, *n.* In *India*, a native groom.

**SYCEE**, *n.* In *China*, silver

**SYCEE-SILV'ER**, *n.* In the form of small half globes, or balls, bearing the

official stamp to testify its purity; and used as the only silver currency of the Chinese, of native make.

**SYCHEE**, *n.* The Chinese name for black tea.

**SYC'ITE**, *n.* [*Gr. συκίτης, a fig*.] Fig-stone; a name which some authors give to nodules of flint or pebbles which resemble a fig.

**SYCO'MA**, *n.* [*from Gr. συκος, a fig*.] A wart or excrescence, resembling a fig, on the eyelid, the anus, or any other part.

**SYCO'NUS**, *n.* In *bot.*, a fleshy, hollow receptacle, containing numerous flowers which are combined in the fruit, as in the fig.

**SYC'OPHANCY**, *n.* [*infra*.] Originally, information of the clandestine exportation of figs; hence, mean talebearing; obsequious flattery; servility.

**SYC'OPHANT**, *n.* [*Gr. συκοφαντης, sycophantes*, a fig, and *φαινω, to discover*.] Originally, an informer against those who stole figs, or exported them contrary to law, &c., at Athens. Hence in time it came to signify a talebearer or informer, in general; hence, a parasite; a mean flatterer; especially a flatterer of princes and great men; hence, a deceiver; an impostor. Its most general use is in the sense of an obsequious flatterer or parasite.

**SYC'OPHANT**, *v. t.* To play the **SYC'OPHANTIZE**, *v.* sycophant; to flatter meanly and officiously; to inform or tell tales for gaining favour. [*Inelegant words*.]

**SYLLAB'ICALLY**, *adv.* In a syllabic manner.

**SYLLABICA'TION**, *n.* The act of forming syllables; the act or method of dividing words into syllables.

**SYL'LABLE**, *n.* [*L. syllaba*; *Gr. συλλαβη, from συλλαμβαναι, to comprehend; συ, and λαμβαναι, to take*.] 1. A letter, or a combination of letters, uttered together, or at a single effort or impulse of the voice. A vowel may form a syllable by itself, as *a*, the definite, or in *amen*; *e* in *even*; *o* in *over*, and the like. A syllable may also be formed of a vowel and one consonant, as in *go, do, in, at*; or a syllable may be formed by a vowel with two articulations, one preceding, the other following it, as in *can, but, tun*; or a syllable may consist of a combination of consonants, with one vowel or diphthong, as *strong, short, camp, voice*.

## SYLLOGISM

A syllable sometimes forms a word, and is then significant, as, in *go, run, write, sun, moon*. In other cases, a syllable is merely a part of a word, and by itself is not significant. Thus *ac*, in *active*, has no signification. At least one vowel or open sound is essential to the formation of a syllable; hence in every word there must be as many syllables as there are single vowels, or single vowels and diphthongs. A word is called according to the number of syllables it contains; viz., monosyllable, a word of one syllable; dissyllable, a word of two syllables; trisyllable, a word of three syllables; polysyllable, a word of many syllables.—2. A small part of a sentence or discourse; something very concise. This account contains not a *syllable* of truth.

Before a *syllable* of the law of God was written. *Hooker.*

**SYLLABUB**, *n.* A compound drink made of wine and milk; a different orthography of *Sillabub*.

**SYLLABUS**, *n.* [L. from the same source as *syllable*.] An abstract; a compendium containing the heads of a discourse; a course of lectures, a book, &c.

**SYLLEPSIS**, *n.* [Gr. *συλλεψις*. See *SYLLEPSIS*.] 1. In *gram.*, a figure by which we conceive the sense of words otherwise than the words import, and construe them according to the intention of the author; otherwise called *substitution*.—2. The agreement of a verb or adjective, not with the word next to it, but with the most worthy in the sentence; as, *rex et regina beati*.

**SYLLEPTICAL**, *a.* Relating to or implying syllepsis.

**SYLLEPTICALLY**, *adv.* By way of syllepsis.

**SYLLOGISM**, *n.* [L. *sylogismus*; Gr. *συλλογισμός*; *συ*, with, and *λογω*, to speak; *λογίζομαι*, to think.] A form of reasoning or argument, consisting of three propositions, of which the two first are called the *premises*, and the last the *conclusion*. In this argument, the conclusion necessarily follows from the premises; so that if the two first propositions are true, the conclusion must be true, and the argument amounts to demonstration. Thus, a plant has not the power of locomotion; an oak is a plant; therefore an oak has not the power of locomotion. These propositions are denominated the *major*, the *minor*, and the *conclusion*. The three propositions of a syllogism are made up of three ideas or terms, and these terms are called the *major*, the *minor*, and the *middle*. The subject of the conclusion is called the *minor term*; its predicate is the *major term*, and the middle term is that which shews the connection between the *major* and *minor term* in the conclusion; or it is that with which the *major* and *minor terms* are respectively compared. Syllogisms are divided by some into single, complex, conjunctive, &c., and by others into categorical, hypothetical, conditional, &c. The figure of a syllogism is the proper disposition of the middle term with reference to the *major* and *minor terms*. The figures are generally reckoned three. The mood of a syllogism is the designation of its three propositions, according to their quantity and quality. The quantity and quality of propositions, in logic, are marked by arbitrary symbols, as A, E, I, O. Every

## SYLVAN

assertion may be reduced to one of four forms—the universal affirmative, marked by A; the universal negative, marked by E; the particular affirmative, marked by I; and the particular negative, marked by O. From these, by combination, all syllogisms are derived. In order to remember the figures, certain words have been long used by writers on logic, which make a grotesque appearance; but which nevertheless are of considerable use. Thus, under the first figure, we have Barbara, Celarent, Darii, Ferio; under the second, Cesare, Camestres, Festino, Baroko; and under the third, Darapti, Disamis, Datisi, Felapton, Bokardo, Feriso. Each of these words designates a particular mood. The rules of syllogism may be thus briefly expressed:

1. One at least of the premises must be affirmative, and one at least universal; 2. The middle term must enter universally in one of the premises; and, 3. The conclusion must not speak of any term in a wider sense than it was spoken of in the premise in which it entered. A term universally spoken of is either the subject of a universal affirmative, or the predicate of any negative. Syllogisms are nothing else than reasoning reduced to form and method, and all that passes under the name of reasoning, unless it can be made syllogistic, is no reasoning at all, but a mass of words without meaning. The syllogism is the instrument of self-examination, and the last weapon of resort in dispute; and a bad syllogism, with one of the premises implied only, and not expressed, is the first resource of fallacy. To bring forward the suppressed premise, is the visible destruction of every argument which is logically bad.

**SYLLOGISTIC**, *a.* Pertaining to a syllogism; consisting of a syllogism; or of the form of reasoning by syllogisms; as, *syllogistic arguments* or reasoning.

**SYLLOGISTICALLY**, *adv.* In the form of a syllogism; by means of syllogisms; as, to reason or prove *syllogistically*.

**SYLLOGIZATION**, *n.* A reasoning by syllogisms.

**SYLLOGIZE**, *v. t.* To reason by syllogisms.

Men have endeavoured to teach boys to *syllogize*, or to frame arguments and refute them, without real knowledge. *Watts.*

**SYLLOGIZER**, *n.* One who reasons by syllogisms.

**SYLLOGIZING**, *ppr.* Reasoning by syllogisms.

**SYMBOL**, *n.* [L. *symbolum*; Gr. *συμβολή*; *συ*, with, and *βάλλω*, to throw; *συμβάλλω*, to compare.] 1. The sign or representation of any moral thing by the images or properties of natural things. Thus the lion is the *symbol* of courage; the lamb is the *symbol* of meekness or patience. Symbols are of various kinds, as types, enigmas, parables, fables, allegories, emblems, hieroglyphics, &c.

—2. An emblem or representation of something else. Thus in the eucharist, the bread and wine are called *symbols* of the body and blood of Christ.—3. A letter or character which is significant. The Chinese letters are most of them *symbols*. The *symbols* in algebra are arbitrary.—4. In medals, a certain mark or figure representing a being or thing, as a trident is the *symbol* of Neptune, the peacock of Juno, &c.—5. Among Christians, an abstract or compendium; the creed or a summary of the articles of religion.—6. *Lot*; sentence of adjudication.—*Mathematical symbols*, letters and characters which represent quantities or magnitudes, and point out their relations. The symbols generally recognized by mathematicians, consist of the capitals of the Roman alphabet, and the small letters of the Italic; the small letters of the Greek alphabet, and such capitals as are distinguishable from the corresponding Roman ones; the Arabic numerals and occasionally the Roman ones; accents, figures and letters, superfixes and

suffixed; as,  $a'$ ,  $a_1$ ,  $a_2$ ,  $a_m$ ,  $a_n$ ; the signs,  $+$ ,  $-$ ,  $\times$ ,  $\div$ ,  $:$ ,  $\sqrt{\quad}$ ; the integral sign  $\int$  with its limits expressed; as, in  $\int_a^b$ ; the symbols of nothing and infinity, 0 and  $\infty$ ; brackets and parentheses, &c., [ ], ( ), { }, &c.; the sign of equality  $=$ ; the signs of greater and less,  $>$ ,  $<$ .—*Chemical symbols*. [See *under* *CHEMICAL*.] In *Scots law*, heritable property is transferred by the delivery of symbols. Thus, lands are resigned by a vassal to his superior by the symbol of *staff and baton*. In giving sasine of lands, the symbols are *earth and stone* of the lands; of an annual rent out of lands, *earth and stone*, with a *penny money*; of fishings, *net and cobble*; of mills, *clap and hopper*; of houses within a burgh, *hasp*

## SYMMETRICAL

and staple; of patronage teinds, a sheaf of corn; of patronage, a psalm-book, and the keys of the church; of jurisdictions, the book of court. The law, however, regarding the transference of heritable property, has recently been much simplified, and many of these symbolical acts are no longer requisite. [See *SABINE*.]

**SYMBOLIC**, } *a.* Representative;  
**SYMBOLICAL**, } exhibiting or expressing by resemblance or signs; as, the figure of an eye is *symbolical* of sight and knowledge. The ancients had their *symbolical* mysteries.

The sacrament is a representation of Christ's death, by such *symbolical* actions as he appointed. *Taylor*.

*Symbolical philosophy*, is the philosophy expressed by hieroglyphics.—*Symbolical books*, the name given by the Lutherans to their standard books of faith and discipline, and now by extension applied to the standards of other bodies of Christians.—*Symbolical attributes*, certain symbols, by which artists distinguish the various evangelists, apostles, saints, &c., in their representations.

**SYMBOLICALLY**, *adv.* By representation or resemblance of properties; by signs; typically. Courage is *symbolically* represented by a lion.

**SYMBOLICS**, *n.* The name given by the Germans to the study of the symbols and mysterious rites of antiquity; and also the study of the history and contents of christian creeds and confessions of faith.

**SYMBOLISM**, *n.* Among chemists, consent of parts.

**SYMBOLIZATION**, *n.* [See *SYMBOLIZE*] The act of symbolizing; resemblance in properties.

**SYMBOLIZE**, *v. i.* [Fr. *symboliser*.] To have a resemblance of qualities or properties.

The pleasing of colour *symbolizeth* with the pleasing of a single tone to the ear; but the pleasing of order doth *symbolize* with harmony. *Bacon*.

They both *symbolize* in this, that they love to look upon themselves through multiplying glasses. *Howell*.

**SYMBOLIZE**, *v. t.* To make to agree in properties.—2. To make representative of something.

Some *symbolize* the same from the mystery of its colours. *Brown*.

**SYMBOLIZED**, *pp.* Made to agree in properties.

**SYMBOLIZING**, *ppr.* Representing by some properties in common; making to agree or resemble in properties.

**SYMBOLOGY**, *n.* The art of expressing by symbols.

**SYMMETRICAL**, *a.* [from *symmetry*.] Commensurable.

**SYMMETRIAN**, } *n.* [from *symmetry*.]  
**SYMMETRIST**, } One eminently studious of proportion or symmetry of parts.

**SYMMETRICAL**, *a.* [from *symmetry*.] Proportional in its parts; having its parts in due proportion, as to dimensions; as, a *symmetrical* body or building; having that obvious relation of equal and similar figures, which refers to their position merely, and consists in their corresponding portions being placed on different sides of the same straight line.—2. In *bot.*, flowers are *symmetrical* when the segments of the calyx, the petals and the stamens are regular, equal, and alike.—3. In *ancient geometry*, commensurable; thus, two

## SYMMETRY

magnitudes, which admitted of a common measure, were said to be *symmetrical*.—*Symmetrical solids*, a name given by Legendre to these solids which, though equal and similar, cannot be made to coincide, or to fill the same space, as is the case with equal and similar plane figures. If a regular pyramid, having for its base an isosceles triangle, be cut by a plane passing through its vertex, and bisecting the base of the isosceles triangle, and also passing through the opposite angle of the same triangle, the figures on each side of the cutting plane will be *symmetrical solids*. The two hands furnish an example of *symmetrical solids*; they give the idea of equality of size, similarity of form, and symmetry of disposition, but yet they cannot be made to coincide or occupy the same space; so as, for instance, to fit exactly the same glove. In *alge*, a function is said to be *symmetrical* with respect to any two letters, when it would undergo no change if these letters were interchanged, or if each were made to take the place of the other. Also, an expression is said to be *symmetrical* with respect to any number of letters, when any two of them whatsoever may be interchanged without alteration of the function.

**SYMMETRICALLY**, *adv.* With due proportion of parts.

**SYMMETRICALNESS**, *n.* State or quality of being symmetrical.

**SYMMETRIZE**, *v. t.* To make proportional in its parts; to reduce to symmetry.

**SYMMETRIZED**, *pp.* Made proportional.

**SYMMETRIZING**, *ppr.* Reducing to symmetry.

**SYMMETRY**, *n.* [Gr. *συμμετρία*: *συμ*, with, together, and *μετρος*, measure; *μετρος*, to measure; Fr. *symetrie*.] A due proportion of the several parts of a body to each other; adaptation of the dimensions of the several parts of a thing to each other; or the union and conformity of the members of a work to the whole.—2. That relation of equal and similar figures which refers to their position merely, and consists in their uniformity as regards the answering of one portion to another, or in their corresponding portions being similarly placed on different sides of the same straight line, so that coincidences cannot be obtained without turning one figure round that straight line. If the front of a building be *symmetrical*, and a vertical line be drawn through the middle of the elevation, then the two lateral portions are not only equal and similar, but also *symmetrical*; the right hand side stands in the right hand portion of space with respect to the dividing line, and in exactly the same manner as the left-hand side stands in the left-hand portion of space. In the letter W there is a want of *symmetry*, but not in O: to make W *symmetrical*, both the inner lines should be made thin, and both the outer ones thick.—3. In the *fine arts generally*, proportion; harmony; the most proper relation of the measure of parts to each other, and to the whole. In the same sense we speak of the *symmetry* of animal bodies.—*Uniform symmetry*, in architecture, is where the same ordonnance reigns throughout the whole.—*Respective symmetry*, is where only the opposite sides are equal to each other.

## SYMPATHIZE

**SYMPATHETIC**, } *a.* [Fr. *sym-*  
**SYMPATHETICAL**, } *pathique*. See *SYMPATHY*.] 1. Pertaining to sympathy.

—2. Having common feeling with another; susceptible of being affected by feelings like those of another, or of feelings in consequence of what another feels; as, a *sympathetic* heart.—3. In *med.*, the term *sympathetic* is applied to symptoms and affections, which occur in parts more or less remote from the primary seat of disease, and are occasioned by some nervous connection of the parts. A disease which is immediately preceded and occasioned by another disease, is sometimes said to be *sympathetic*, in contradistinction from *idiopathic*, which is applied to a disease not preceded or occasioned by any other; but, in this case, the term *sympathetic* is not only more appropriate, but more commonly employed.—4. Among *alchemists*, an epithet applied to a kind of powder, possessed of the wonderful property that if spread on a cloth dipped in the blood of a wound, the wound will be healed, though the patient is at a distance. This opinion is discarded as charlatany.—5. In *anat.*, the term *sympathetic* is applied to that system of nerves, which takes its origin from the semilunar ganglion in the centre of the epigastrium, and is sent to the whole nutritive system, and also to the organs of reproduction.—*Sympathetic ink*, a species of ink or liquor with which, when a person writes upon paper, the writing is invisible until heat or some re-agent is applied. Most of the acids or saline solutions, being diluted and used to write with, become visible by heating before the fire. A diluted solution of cobalt affords an ink which becomes green when held before the fire. If a weak solution of galls be used, the writing will be invisible till the paper is moistened with a weak solution of sulphate of iron. The diluted solutions of gold and silver remain colourless upon the paper till exposed to the sun's light.—*Sympathetic sounds*, sounds produced in one musical instrument by sounding another near it. The harmonies of the Æolian harp are *sympathetic* sounds, being produced by the communication of motion from one string to another, through the medium of intervening air.—*Sympathetic disease*, one which is produced by a remote cause, as when a fever follows a local injury.—*Sympathetic cures*, cures pretended or real, the operation of which is attributed to a certain sympathy of the sufferer with other individuals, or with spirits, animals, stars, plants, &c. A full belief in the efficacy of such means of cure, has a great effect in such diseases as are seated in the nervous system.—*Sympathetic powder*, a powder chemically prepared from green or blue vitriol.

**SYMPATHETICALLY**, *adv.* With sympathy or common feeling; in consequence of sympathy; by communication from something else.

**SYMPATHIST**, *n.* One who feels sympathy.

**SYMPATHIZE**, *v. i.* [Fr. *sympathiser*. See *SYMPATHY*.] 1. To have a common feeling, as of bodily pleasure or pain.

The mind will *sympathize* so much with the anguish and debility of the body, that it will be too distracted to fix itself in meditation. *Buckminster*.

## SYMPHONY

2. To feel in consequence of what another feels; to be affected by feelings similar to those of another, in consequence of knowing the person to be thus affected. We *sympathize* with our friends in distress; we feel some pain when we see them pained, or when we are informed of their distresses, even at a distance. It is generally and properly used of suffering or pain, and not of pleasure or joy. It may be sometimes used with greater latitude.—3. † To agree; to fit.

**SYMPATHIZING**, *ppr.* Feeling mutually, or in consequence of what another feels.

**SYMPATHY**, *n.* [Gr. *συμπαθία*, *συμπαθίζω*: *συμ*, with, and *παθω*, passion.] 1. Fellow feeling; the quality of being affected by the affection of another, with feelings correspondent in kind, if not in degree. We feel *sympathy* for another when we see him in distress, or when we are informed of his distresses. This *sympathy* is a correspondent feeling of pain or regret. *Sympathy* is often an imitative faculty, sometimes exercised involuntarily, frequently without consciousness. Thus we yawn when we see others yawn, and are made to laugh by the laughing of another.

*Sympathy* is produced through the medium of organic impression. *Chippens.*

I value myself upon *sympathy*; I hate and despise myself for envy. *Kamra.*

2. An agreement of affections or inclinations, or a conformity of natural temperament, which makes two persons pleased with each other.

To such associations may be attributed most of the *sympathies* and antipathies of our nature. *Aum.*

3. In *med.*, a correspondence of various parts of the body in similar sensations or affections; or an affection of the whole body or some part of it, in consequence of an injury or disease of another part, or of a local affection. Thus, a contusion on the head will produce nausea and vomiting. This is said to be by *sympathy*, or consent of parts.—4. In *nat. hist.*, a propension of inanimate things to unite, or to act on each other. Thus we say, there is a *sympathy* between the lodestone and iron.—5. In the *fine arts*, conformity of the parts to each other; but in *painting*, it usually signifies the effective union of colours.

**SYMPER'SIS**, *n.* In *med.*, a ripening of inflammatory humours.

**SYMPHONIA**, *n.* [L.] A symphony.

**SYMPHONIOUS**, *a.* [from *sympphony*.] Agreeing in sound; accordant; harmonious.

## Sounds

*Symphonious* of ten thousand harps. *Milton.*

**SYMPHONIST**, *n.* A composer of symphonies or instrumental music.

**SYMPHONIZE**, *v. i.* To agree with; to harmonize.

**SYMPHONY**, *n.* [L. *symphonia*; Fr. *symphonie*; Gr. *συμφοניה*: *συμ*, with, and *φωνη*, voice.] 1. A consonance or harmony of sounds, agreeable to the ear, whether the sounds are vocal or instrumental, or both.

The trumpets sound,

And warlike *symphony* is heard around. *Dryden.*

2. An ancient musical instrument, supposed by some to be of the lyre kind, and by others a sort of drum, used as an accompaniment.—3. In *modern usage*, a musical composition for a full band of instruments, and formerly

## SYMPOCE

called an overture. It generally consists of four movements; a brilliant allegro, which is commonly preceded by a short, serious, slow introductory movement; an andante varied, or an expressive adagio; a minuet with its trio; and a finale of rapid motion. The term *symphony* is also applied to an instrumental passage which usually introduces a piece of vocal music, or is brought in at the close, or occurs during some pause of the voice. Haydn, Mozart, and Beethoven, are the greatest modern composers of symphonies.

**SYMPHORICARPOS**, *n.* A genus of **SYMPHORIA**, } plants, nat.

order Caprifoliaceæ, the species of which are natives of North and South America. They are elegant bushy shrubs, with small white or rose-coloured flowers. *S. vulgaris* is known by the name of common St. Peter's wort, and *S. racemosus* by that of snowberry. This latter has become very common in our gardens.

**SYMPHYSIS**, *n.* [Gr. *συμφυσις*: *συμ*, together, and *φυω*, to grow.] 1. In *anat.*, the union of bones by cartilage; a connection of bones without a movable joint.—2. In *sur.*, a coalescence of a natural passage; also, the first intension of cure in a wound.

**SYMPHYTUM**, *n.* A genus of plants, nat. order Boraginaceæ. The species are rough herbaceous plants, with broad leaves and terminal twin racemes of flowers. They inhabit chiefly Europe and Asia. *S. officinalis*, or common comfrey, is found in Britain on the banks of rivers and ditches. Its root abounds in a mucilage, which is useful in irritations of the throat, intestines, and bladder. There are several other species.

**SYMPIESOMETER**, *n.* [Gr. *συμπίεζω*, to compress, and *μετρον*, measure.] A kind of barometer, contrived by Mr. Adie of Edinburgh, for measuring the weight of the atmosphere by the compression of a column of gas. It consists of a glass tube about 18 inches long, having the lower end bent up like the tube of the wheel barometer, each end being terminated by an elongated bulb. The upper end is hermetically sealed, but the lower end is left open. The upper part of the tube is filled with hydrogen gas, and the lower part with some fixed oil. The pressure of the atmosphere is exerted upon the surface of the oil, which is exposed to it in the turned up open end of the tube. This pressure causes the oil to stand at a certain height in the tube, and to produce a certain compression in the column of hydrogen gas. As the atmospheric pressure becomes greater, the oil will rise, and the gas will be compressed into less space. The change in the bulk of the gas caused by a change in the atmospheric pressure is measured by a scale. The *sympiesometer* is a useful instrument, but inferior in accuracy to the common barometer.

**SYMPLSITE**, *n.* In *min.*, a mineral of an indigo colour.

**SYMPOCARPUS**, *n.* A genus of plants belonging to the nat. order Araceæ. The *S. fetida*, skunk cabbage, is a powerful antispasmodic, and also an expectorant. It has a considerable reputation in North America as a palliative in paroxysms of asthma.

**SYMPOCE**, *n.* [Gr. *συμπλοκή*: from *συμ*, together, and *πλοκή*, a twisting or

## SYN

folding.] In *rhet.*, a figure where several sentences or clauses have the same beginning and the same end.

**SYMPOCEOS**, *n.* A genus of plants belonging to the nat. order Styracææ. The species are trees inhabiting North and South America, and tropical Asia. They all possess an astringent principle in their leaves, and some, as *S. tinctoria*, dyer's *symplocos*, sweet leaf or yellow leaf, are used in dyeing.

**SYMPO'SIA**, *n. plur.* [Gr. *συμμοσία*, a feast.] The feasts of the ancient Greeks.

**SYMPOSIAC**, *a.* (*sympo'ziao*.) [Gr. *συμμοσιας*, a drinking together; *συμ*, together, and *πιω*, to drink.] Pertaining to computations and merry-making; happening where company is drinking together; as, *symposiac* meetings.

*Symposiac* disputations. [Not much used.] *Arbut. hnut.*

**SYMPO'SIAC**, *n.* A conference or conversation of philosophers at a banquet.

**SYMPO'SIARCH**, *n.* [Gr. *συμμοσιαρχης*, a feast, and *αρχης*, a ruler.] In *antiquity*, the director or manager of a feast, who was sometimes appointed by the person at whose charge the entertainment was made, or selected by the suffrages of the party.

**SYMPOS'LAST**, *n.* One who drinks or makes merry with others.

**SYMPOSIUM**, *n.* (*sympo'zium*.) [*supra*.] A drinking together; a merry feast.—2. A banquet among philosophers.

**SYMPTOM**, *n.* [Fr. *symptome*; Gr. *συμπτωμα*, a falling or accident, from *συμ*, with, and *πτωω*, to fall.] 1. Properly, something that happens in concurrence with another thing, as an attendant. Particular *symptoms*, which more uniformly accompany a morbid state of the body, and are characteristic of it, are called *pathognomonic*, or *diagnostic symptoms*. *Symptoms* are best divided into *essential*, which are peculiar to certain diseases; *accidental*, produced by some circumstance of unusual occurrence; and *common*, which are met with alike in various complaints.—2. Authors are not agreed about the time when the Jews first began to have synagogues. Some suppose them as old as the ceremonial law, and others fix their beginning after the return of the Jews from the Babylonish captivity. Synagogues were erected not only in towns and cities, but also in the country, especially near rivers, that they might have water for their purifications and ceremonies. Jerusalem is said to have contained 480 synagogues. The synagogue was governed by a council or assembly, over whom was a president called the ruler of the synagogue. The service consisted of prayers, reading the Scriptures, and preaching and expounding of them. The chief ruler, or one of the council, gave permission to read and expound the law, and appointed who should do it. The synagogue service was at first confined to the Sabbath days and festivals, but was latterly extended to Mondays and Thursdays.—3. **SYN'OD**, *n.* [Gr. *synodos*, a convention, *syn* and *odos*, way.] 1. In *church history*, a council or meeting of ecclesiastics to consult on matters of religion. Synods are of four kinds, 1. *General* or *ecumenical*, which are composed of bishops from different nations. 2. *National*, in which the bishops of one nation only meet, to determine points of doctrine or discipline. 3. *Provincial*, in which the bishops of one province only meet. This is called a convocation. 4. *Diocesan*. In the established church of Scotland, a provincial synod is one of the church courts, composed of the several presbyteries within the bounds prescribed by the general assembly, or of the ministers and elders who stand on the roll as constituent members of such presbyteries. The synod is a court of review immediately above the presbytery. Its meetings are generally held twice a year, though in some remote districts only once. Every ecclesiastical question which has been under the consideration of a presbytery within the provincial district, may be competently brought under the review of the synod. It has, besides, an original jurisdiction, as well on subjects of general interest, as with regard to the conduct of its own members, and can both give authoritative directions to the presbyteries, and originate propositions to the general assembly on any subject which seems to require its influence or authority. On the other hand, every judgment of a synod as an inferior court, may be brought under the review of the general assembly by reference, complaint, or appeal. But in every question, not carried to the general assembly, the judgment of the synod (if it has not gone beyond its jurisdiction) is final. Synods whose boundaries are contiguous correspond with one another, by sending one minister and one elder, who are entitled to sit and vote with the other members of the synod to which they are sent. The number of synods is sixteen. The synod is opened by the moderator of the preceding synod, and after the roll is made up, a new moderator, who must be a minister, is elected. Other presbyterian bodies have synods, which are similarly constituted. The convocations of the English clergy are provincial synods, but they have virtually expired.—2. A meeting, convention, or council; as, a *synod* of gods.

Let us call to *synod* all the blest. *Milton*.

the moon with the sun to another. This is called also a *lunation*, because in the course of it the moon exhibits all its phases. This month consists of 29 days, 12 hours, 44 minutes, 237 seconds.—*Synodic revolution of a planet*, with respect to the sun, is the period which elapses between two consecutive conjunctions or oppositions. The duration of this period is easily determined when the difference between the mean motion of the planet and sun, in a given interval of time, is known; for this difference is to 360° as the given interval to the synodic revolution.

**SYNONYMALLY**,† *adv.* Synonymously.

**SYN'ONYME**, } *n.* [Gr. *synonymos*: *syn*,  
**SYN'ONYM**, } with, and *onoma*, name.]

A name, noun, or other word having the same signification as another, is its *synonym*. Thus valour and courage, are regarded as synonyms; so also, virtue and goodness; vice and wickedness. Strictly speaking, words having exactly the same signification do not exist in any language. Different dialects of the same language may indeed have different words of the same meaning, but as soon as these pass from the dialect into the literary or generally adopted language, they either take the place of some other word of the same signification, or receive themselves a new shade of meaning, and are then added to the others. Still, it is true, that the similarity in the meaning of words is often so great, that much discrimination is required to ascertain the different shade of each word. Such words may be frequently used for one another, and this interchange produces a pleasing variety in composition, and is necessary in poetry. Synonyms form an important object of philological study, and demand, on the part of the inquirer, great knowledge of the principles of language. Blair, Booth, and Craik have written on English synonyms.

He has extricated the *synonyms* of former authors. *Care's Russ*.

**SYNONYMI***ST*, *n.* One who synonymizes. Specially, among *botanists*, a person who collects the different names or synonyms of plants, and reduces them to one another.

**SYNONYMI***ZE*, *v. t.* To express the same meaning in different words.

**SYNONYMI***ZED*, *pp.* Expressed in different words.

**SYNONYMI***ZING*, *ppr.* Expressing the same thing in different words.

**SYNONYMOUS**, *a.* Expressing the same thing; conveying the same idea.

We rarely find two words precisely *synonymous*. *Wave* and *billow* are sometimes *synonymous*, but not always. When we speak of the large rolling swell of the sea, we may call it a *wave* or a *billow*; but when we speak of the small swell of a pond, we may call it a *wave*, but we may not call it a *billow*.

In *chem.*, the uniting of elements into a compound; the opposite of *analysis*, which is the separation of a compound into its constituent parts. **SYRINGE**, *n.* (*sy'rix*.) [supra.] A portable hydraulic instrument of the pump kind, commonly employed to draw in a quantity of water or other fluid, and to squirt or eject the same with violence. In its simplest form it consists of a small cylindrical tube with an air-tight piston or sucker, to the rod of which a ring or other convenient handle is attached. The lower end of the cylinder terminates in a small tube, which being immersed in any fluid, and the piston then drawn up, the fluid is forced into the body of the cylinder by the atmospheric pressure. By pushing back the piston to the bottom of the cylinder, the contained fluid is expelled in a small jet, and with a force proportioned to the power applied to the piston. The syringe acts on the principle of the sucking pump, and is used by surgeons, &c., for washing wounds, for injecting fluids into animal bodies, and other purposes. It is also employed as a pneumatic machine for condensing or exhausting the air in a close vessel, but for this purpose two valves are necessary. In the condensing syringe the valves open downwards and close upwards; but in the exhausting syringe they open upwards, and close downwards, as in the common air-pump.

**SYRINGODENDRON**, *n.* [Gr. *syrix*, a pipe, and *dendron*, a tree.] The name given by Count Sternberg to many species of *Sigillaria*, (a genus of extinct fossil trees,) on account of the parallel pipe-shaped flutings, which extend from the top to the bottom of their trunks. Those trunks are without joints, and many of them attain the size of forest trees.

[*Not English.*] The Greeks and Romans gave the name *syrtis* to the two gulfs on the northern coast of Africa, one of which they called *Syrtis major*, and the other *Syrtis minor*. Both were the terror of the ancient mariners from their drawing in ships, and swallowing them up in their sandy shoals. The greater syrtis is now called the gulf of Sidra, and the lesser the gulf of Khabs.

**SYRUP**, or **SIRUP**, *n.* [*Fr. syrup*; *Low L. sirupus*, or *syrrupus*; from *Gr. σικκος* *sikos*, *succus syriacus*, because the use of syrups originated with the Syrians. But perhaps the word is derived from Arab. *sirab*, a drink, a potion, a medicated drink; *Ar. sherdh*, a beverage; *shardubh*, a draught.] Syrups are medicinal solutions of sugar, either in water alone, as in simple syrup, or in liquids charged with some peculiar principle of an active kind, such as senna or buckthorn, or merely grateful from their colour or fragrance, or both; such as syrup of violets. There is almost an endless variety of syrups, but few of them possess medicinal properties to any important extent. **SYRUPED**, or **SIRUPED**, *a.* Moistened or tinged with syrup.

**SYRUPY**, or **SIRUPY**, *a.* Like syrup, or partaking of its qualities.

**SYSSARCO'SIS**, *n.* [*Gr. συρ, with, and σαρξ*, flesh.] A species of union of bones, in which one bone is united to another by means of an intervening muscle.

**SYSTALTIC**, *a.* In *med.*, having alternate contraction and dilatation.

**SYSTASIS**, *n.* [*Gr. συστασις*.] The consistence of a thing; constitution. [*Little used.*]

**SYSTEM**, *n.* [*Fr. système*; *L. systema*; *Gr. συστημα*; *συν* and *ιστημι*, to set.] 1. Any combination of things acting together; an assemblage of things adjusted into a regular whole; or a whole plan or scheme consisting of many parts connected in such a manner as to create a chain of mutual dependences; or a regular union of principles or parts forming one entire thing; or an assemblage of facts, or of principles and conclusions scientifically arranged, or disposed according to certain mutual relations, so as to form a complete whole. Thus we say, a *system of logic*, a *system of philosophy*, a *system of government*, a *system of principles*, the *solar system*, the *Copernican system*, a *system of divinity*, a *system of law*, a *system of morality*, a *system of husbandry*, a *system of botany* or of chemistry. *System* is sometimes nearly synonymous with *classification*, and sometimes with *hypothesis* or *theory*. Thus we speak of a *mythological system*, or a *chronological system*, in the historical sciences; of a *botanical system*, or a *mineralogical system*, in natural science; and of the *Copernican*, *Ptolemaic*, or *Tychonic system*, in astronomy. The purpose of a system is to classify the individual subjects of our knowledge in such a way as to enable us readily to retain and employ them, and at the same time to illustrate each by showing its connection with all. The constituent

## SYSTEMATIC

parts of a system are a fundamental principle which serves as a basis for the whole, and a large collection of facts, from which the various laws are to be deduced, which themselves all flow together into the common principle.—2. Regular method or order.—3. In *astron.*, any hypothesis or theory of the disposition and arrangements of the heavenly bodies, by which their phenomena, their motions, changes, &c., are explained. When such a theory embraces only the sun and the planetary bodies connected with him, it is termed the *solar* or *planetary system*; but when it embraces the fixed stars also, or the whole material creation generally, it is termed a *system of the universe*, or of the *world*. The most celebrated systems of the world are the following:—1. The *Ptolemaic system*, framed by the Greek astronomer Ptolemy. According to this system, the earth is an absolutely fixed centre, and the heavens are considered as revolving about it from east to west, and carrying along with them all the heavenly bodies, the stars and planets, in the space of twenty-four hours. 2. The *Copernican system*, taught by Copernicus in the beginning of the 16th century. According to this system, the sun is supposed to be at rest in the centre of the universe, and the earth and the several planets to revolve about him as a centre, while the moon and the other satellites revolve about their primaries in the same manner. The heavens and fixed stars are here supposed to be at rest, and their apparent diurnal motions are imputed to the earth's motion from west to east. 3. The *Tychonic system*, proposed by Tycho de Brahe, towards the latter end of the 16th century. According to this system, the sun is a centre of motion to all the planets which revolve round it, while the sun and planetary orbits are carried together round the earth as a fixed centre. 4. The *Newtonian system*, so named as being adopted by Sir Isaac Newton. In this system there is no fixed centre, the sun only approximating to that character from its greater magnitude. The orbits of the planets, which all revolve round the sun, are approximately represented by ellipses, exactly by ellipses of which the elements vary. The *Newtonian system*, which is the only one admitted in modern astronomy, is frequently called the *Copernican*, from its rejecting what Copernicus rejected, but it is far from receiving all that Copernicus received. The term *system* is frequently applied to the subdivisions of the solar system; thus we have the *terrestrial*, *Jovial*, *Saturnian*, *Uranian systems*.—4. In *anat.* and *phys.*, an assemblage of parts or organs which are essentially necessary to the performance of some animal function, as the *absorbent system*, the *nervous system*, the *vascular system*. The whole human body, as an assemblage of parts, is also often termed the *system*.—5. In the *fine arts*, a collection of the rules and principles upon which an artist works.—6. In *music*, an interval compounded or supposed to be compounded of several lesser intervals, as the fifth, octave, &c., the elements of which are called *diatems*.

**SYSTEMATIC**, *a.* Pertaining to **SYSTEMATICAL**, *a.* system; consisting in system; methodical; formed

## SYZYGY

with regular connection and adaptation or subordination of parts to each other, and to the design of the whole; as a *systematic* arrangement of plants or animals; a *systematic* course of study.—2. Proceeding according to system or regular method; as, a *systematic* writer.

**SYZYGIUM**, *n.* A genus of plants, nat. order Myrtaceae. The species inhabit tropical countries; they are trees or shrubs of a highly ornamental appearance from their smooth shining leaves, which are opposite and entire.—*S. guineense*, which grows on the coast of Guinea and Senegal, has been employed as a remedy in rheumatism.—*S. jambolanum* is extensively cultivated in the East Indies on account of its edible fruit, sometimes called Java plum by Europeans, but Jamoon by the natives. It is of a rich purplish colour, but of a subastringent sweetish taste, which is more agreeable to the native than to the European palate. The bark is astringent, and dyes of a brown colour; the wood is hard and durable, and much employed.

**SYZYGY**, *n.* [*Gr. συζυγία*; *συν* and *ζυγω*, to join.] The conjunction or opposition of a planet with the sun, or of any two of the heavenly bodies. On the phenomena and circumstances of the *syzygies*, depends a great part of the lunar theory.—2. [*L. syzygia.*] In *gram.*, the coupling of different feet together in Greek or Latin verse.

# T

## T

**T** IS the twentieth letter of the English Alphabet, and a close consonant. It represents a close joining of the end of the tongue to the root of the upper teeth, as may be perceived by the syllable *at, et, of, ut*, in attempting to pronounce which, the voice is completely intercepted. It is therefore numbered among the mutes, or close articulations, and it differs from *d* chiefly in its closeness; for in pronouncing *ad, ed*, we perceive the voice is not so suddenly and entirely intercepted, as in pronouncing *at and et*. *T* by itself has one sound only, as in *take, turn, bat, bolt, smite, bitter*. So we are accustomed to speak; but in reality, *t* can be hardly said to have any sound at all. Its use, like that of all mute articulations, is to modify the manner of uttering the vocal sound which precedes or follows it. When *t* is followed by *h*, as in *think* and *that*, the combination really forms a distinct sound for which we have no single character. This combination has two sounds in English; aspirated, as in *think*, and vocal, as in *that*. The letters *ti*, before a vowel, and unaccented, usually pass into the sound of *sh*, as in *nation, motion, partial, substantiate*; which are pronounced *nashon, moshon, parshal, substanshate*. In this case, *t* loses entirely its proper sound or use, and being blended with the subsequent letter, a new sound results from the combination, which is in fact a simple sound. In a few words, the combination of *ti* has the sound of the English *ch*, as in *Christian, mirtion, question*. *T* is convertible with *d*. Thus the Germans write *tag*, where we write *day*, and *gut*, for *good*. It is also convertible with *s* and *z*, for the Germans write *wasser*, for *water*, and *zahn*, for *tame*. *T*, as an abbreviation, stands for *theologia*; as, *S. T. D. sancta theologie doctor*, doctor of divinity. In ancient monuments and writings, *T* is an abbreviation which stands for *Titus, Titius, or Tullius*. As a numeral, *T*, among the Latins, stood for 160, and with a dash over the top, *T̄*, for 160,000. In *music*, *T* is the initial of *tenor*, vocal and instrumental; of *tacet*, for silence, as *adagio tacet*, when a person is to rest during the whole movement. In concertos and symphonies, it is the initial of *tutti*, the whole band, after a solo. It sometimes stands for *tr.* or *trillo*, a shake. —*T-bandage*, a bandage so named from its figure. It is principally used for supporting the dressings after the operation for fistula in the anus, in diseases of the perineum, and those of the groin, anus, &c. —*T-square*, an instrument much used in drawing plans of architectural and mechanical objects. It consists simply of two slips of hard wood or mahogany, *a* and *b*, whose edges are dressed truly straight and parallel; the former, called the *blade*, is much thinner than the *stock*, *b*, into which one of its ex-

## TABBY

tremities is fixed firmly at right angles; consequently, when the stock is applied to the edges of a rectangular board on which the paper is stretched, a pen or pencil pressed tightly against the blade will trace straight lines parallel or at right angles to each other, as may be required. Sometimes a *shifting stock*, *c*, is also applied in the manner represented in the figure for the convenience of drawing oblique lines parallel to each other. **TAB, n.** The latchet of a shoe fastened with a string, or otherwise. [*Local.*] —2. The end of a lace; a tag. [*Local.*] —3. A cap border, worn in the inside of a lady's bonnet. —4. A cup. [*Local.*] **TABANIDÆ, n.** A family of dipterous insects. It was worn over the body armour, and generally emblazoned. At first the *tabard* was very long, reaching to the mid-leg, but it

was afterwards made shorter. It was at first chiefly worn by the military, but afterwards became an ordinary article of dress among other classes in France and England in the middle ages. In this country the *tabard* is now only worn by heralds. **TABARDER, n.** One who wears a tabard. **TABARDEERS, n.** A name formerly given to the scholars at Oxford, who wore the *tabard*. **TABARET, n.** A stout satin-striped silk, used for furniture. **TABASHEER, n.** A Persian word signifying a concretion found in the joints of the bamboo, said by Dr. Russel to be the juice of the plant thickened and hardened; by others, to be pure silex. It is highly valued in the East Indies as a medicine, for the cure of bilious vomitings, bloody flux, piles, &c.; but its medicinal virtues seem to be more imaginary than real. **TAB'BIED, pp.** Watered; made wavy. **TAB'BINET, n.** A more delicate kind of tabby; taffety. **TAB'BY, a.** [See the noun.] Brindled;

## TABERNACLE

brindled; diversified in colour; as, a *tabby cat*. **TABBY, n.** [*Fr. tabis*; *It. Sp. and Port. tabi*; *G. tobis*; *Arm. tastag*, taffeta. *Qu. Fr. taveler*, to spot.] 1. The name formerly given to a kind of rich silk and other stuffs watered or figured, by being passed through a calender, the rollers of which are variously engraved. The engraved parts, pressing unequally upon the stuff, renders the surface unequal, so as to reflect the rays of light differently, and produce the appearance of waves. The same effect may be produced by folding the stuffs in a particular manner, and subjecting them to pressure. —2. A mixture of lime with shells, gravel, or stones in equal proportions, with an equal proportion of water, forming a mass, which when dry, becomes as hard as rock. This is used in Morocco instead of bricks for the walls of buildings. —3. A cat. [*Colloq.*] —4. An old maiden lady; an ancient spinster. [*Little used.*] **TABEL'ION, n.** [*Fr.; L. tabellio*, from *tabula*, a tablet.] A kind of secretary or notary. Such a functionary existed under the Roman empire; and, during the old system, in France. **TAB'ERD.** See *TABARD*. **TAB'ERN, n.** A provincial name for a cellar. **TAB'ERNACLE, n.** [*L. tabernaculum*, a tent, from *taberna*, a shop or shed, from *tabula*, a board; or rather from its root. Among the Jews, a movable building, so contrived as to be taken to pieces with ease and reconstructed, for the convenience of being carried during the wanderings of the Israelites in the wilderness. It was of a rectangular figure, thirty cubits long, ten broad, and ten high. The interior was divided into two rooms or compartments by a veil or curtain, and it was covered with four different spreads or carpets. The outer or larger compartment was called the holy place, being that in which incense was burned, and the shew-bread exhibited; and the inner the most holy place, or holy of holies, in which was deposited the ark of the covenant. The word *tabernacle* is also applied to the temple; Ps. xv. —*Feast of tabernacles*, the last of the three great annual festivals of the Israelites, which required the presence of all the people in Jerusalem. Its object was to commemorate the dwelling of the people in tents during their journeys in the wilderness, and it was also a feast of thanks-

## TABLATURE

giving for the harvest and vintage. It was celebrated in autumn at the conclusion of the vintage, and lasted eight days, during which the people dwelt in booths made in the streets, in courts, or on the tops of their houses, of the leafy branches of certain trees. These booths were intended to represent the tents in which the Israelites dwelt in the wilderness. [See Lev. xxiii.]—4. A small temple; a place of worship; a sacred place. The name *tabes* is now retained for only two forms of disease: 1. *Tabes mesenterica*, that wasting of the body which follows serofulous inflammation of the mesenteric glands; and, 2. *Tabes dorsalis*, which denotes an impairment of general health, attended by emaciation, muscular debility, and signs of nervous exhaustion, occasioned by an inordinate indulgence of the sexual appetite. It is so called from the weakness which it causes in the back and loins.

off, and an arbitrary one substituted. But it is usually applied to a deed framed in terms of the statute 1685, c. 22, and intended for the purpose of securing the descent of an heritable estate to the series of heirs or substitutes called to the succession by the maker of the tailzie. Any person is allowed to tailzie his lands and estates, and to prescribe to the heirs such conditions as he pleases. But to constitute an effectual entail he must prohibit the institute, or person to whom the estate is conveyed, in the first place, and the substitutes, who are afterwards to succeed, from selling, alienating, or disposing the estate, altering the order of succession, or contracting debt, and thereby causing the estate to be adjudged. The clauses essentially necessary to give effect to an entail are, 1st, Prohibitions against altering the order of succession, against alienating the land, and against contracting debts, whereby the lands may be burdened or affected by diligence; 2d, Irritant clauses, declaring that all deeds executed, whereby the course of succession may be altered, or the lands sold or conveyed away, and all debts contracted, contrary to the above prohibitions, shall be void and null; and, 3d, Resolutive clauses, declaring that if any of the heirs of entail shall act contrary to all or any of the prohibitions, he shall forfeit his right to the lands entailed, sometimes for himself only, and in other cases for all the heirs who may take the succession as his descendants. But in the deed of entail, as now in use, a variety of other clauses are usually added. An entail is not effectual till recorded in the register of entails at Edinburgh, and followed by infestment.

A magnesian mineral, consisting of broad, flat, smooth laminae or plates, unctuous to the touch, of a shining lustre, translucent, and often transparent. By the action of fire, the laminae open a little, the fragment swells, and the extremities are with difficulty fused into a white enamel. When rubbed with resin, talc acquires positive electricity. Its prevailing colours are white, apple-green, and yellow. There are three principal varieties of talc, *common*, *earthy*, and *indurated*. Its constituents are silice and magnesia, with small quantities of potash, alumina, oxide of iron, and water. It is used in many parts of India and China, as a substitute for window glass; indurated talc is used for tracing lines on wood, cloth, &c., instead of chalk. Talc is met with in several parts of Scotland, chiefly in connection with serpentine, and on the Continent. Several varieties are found in India and Ceylon.

The Attic talent, the weight, contained 60 Attic minae, or 6000 Attic drachmæ, equal to 56 pounds, eleven ounces, English troy weight. The mina being reckoned equal to £3 4s. 7d. sterling, the talent was of the value of £193 15s. sterling. Other computations make it £243 15s. sterling. The Romans had the great talent and the little talent; the great talent is computed to be equal to £99 6s. 8d. sterling, and the little talent to £75 sterling.—2. *Talent*, among the Hebrews, was also a gold coin, the same with a shekel of gold; called also stater, and weighing only four drachmas. But the Hebrew talent of silver, called *ricar*, was equivalent to three thousand shekels, or ninety-three pounds, twelve ounces avoirdupois, and its value as silver money, £396 5s. 10d.—3. The operation, according to the discoverer's method, is effected by partially detaching a portion of the skin of the arm, moulding it into the proper shape, causing adhesion, and, after a time, finally detaching it from the arm, so that it remains in its new situation. Of late years several successful operations for new noses have been performed, and this is now always done by turning down a flap of integument from the forehead.

When pure, tallow is white and nearly tasteless; but the tallow of commerce usually has a yellow tinge. All the different kinds of tallow consist chiefly of stearine with a little oleine; but that of the goat contains also hircine in small quantity. In com., tallow is divided into various kinds according to its qualities, of which the best are used for the manufacture of candles, and the inferior for making soap, greasing machinery, and several other purposes. Tallow is also much used in the dressing of leather. It is imported in large quantities from Russia. The fat of swine we never call *tallow*, but *lard*. **TAL'LY**, *n.* [*Fr. tailler*, *Port. talhar*, *Sp. tular*, to cut. See **TAIL**.] 1. A piece of wood on which notches or scores are cut, as the marks of number. In purchasing and selling, it was customary for traders to have two sticks, or one stick cleft into two parts, and to mark with scores or notches on each, the number or quantity of goods delivered, or what was due between debtor and creditor, the seller or creditor keeping one stick, and the purchaser or debtor, the other. Before the use of writing, or before writing became general, this or something like it, was the usual method of keeping accounts, and it is still customary among small publicans, milk-men and others, to keep the account or score of a debt by notches. In the Exchequer, *tallies* were formerly used, which answered the purpose of receipts as well as simple records of matters of account. Hence the origin of exchequer *bills*. In former times of financial difficulty, (from the period of the Norman conquest,) the practice had been to issue exchequer *tallies*. An exchequer tally was an account of a sum of money lent to the government, or of a sum for which the government would be responsible. The tally itself consisted of a squared rod of hazel or other wood, having on one side notches, indicating the sum for which the tally was an acknowledgment. On two other sides opposite to each other, the amount of the sum, the name of the payer, and the date of the transaction, were written by an officer called the writer of the tallies. This being done the rod was then cleft longitudinally in such a manner that each piece retained one of the written sides, and one half of every notch cut in the tally. One of these parts was kept in the exchequer, and the other only issued. When the part issued was returned to the exchequer (usually in payment of taxes), the two parts were compared, as a check against fraudulent imitation. Hence our corresponding practice with cheques, and the origin of the term we employ when we say, that a cheque should *tally* with its counterpart. Hence also the terms "*Bill*," Norman French, *bille*, a baton; *billet*, a short piece of wood, and the origin of the phrase, being on the "*staff*," as applied to officers in the pay of the crown. The size of the notches made on the tallies varied with the

amount. The notch for £100 was the breadth of a thumb; for £1 the breadth of a barley corn. A penny was indicated by a slight slit. Clumsy as this contrivance may appear, it was effectual in the prevention of forgery. Tallies were finally discontinued in the exchequer in 1834. The *tellers* of the exchequer derived their name from the word *tally*, teller being originally written *tallier*. Many different kinds of tally are used in gardens and arborescences, for the purpose of bearing either numbers referring to a catalogue, or the names of the plants near which they are placed. It is quite an error to suppose that promissory notes, supported by the credit of government, are a modern invention. They existed for six centuries in this country before the introduction of paper-money; the only difference between the modern and the ancient system is, that the promissory notes which are now made of paper, were formerly made of wood.—2. One thing made to suit another. They were framed the *tallies* for each other.

The goods thus furnished are usually of inferior quality, and the prices exorbitant. The system is fraught with much mischief to those (chiefly mechanics, labourers, porters, &c.) who resort to tally-shops.

**TAL'MUD**, *n.* [Ch. from תורה *lamad*, to teach.] The body of the Hebrew laws, traditions, and explanations; or the book that contains them. small leaflets and racemes of flowers. The *T. indica*, or East Indian tamarind, is a native of various districts of the East Indies, and also of the tropical parts of Africa. It forms a handsome tree, with spreading branches. The *T. occidentalis*, or West Indian tamarind, is distinguished from the other by possessing short legumes. It is a native of South America and the West India islands, forming also a large spreading tree. Both species are cultivated for the sake of their shade, and their cooling, grateful acid fruit, which is a one-celled legume, with from three to six seeds, the valves being filled with pulp between the endocarp and epicarp. The pulp, dried or packed with sugar or syrup, is imported into European countries. [See TAMARINDS.]

**TAMARINDS**, *n. plur.* The preserved fruit of the East and West Indian tamarind trees; that of the former being much larger than that of the latter. Tamarinds have a sharp, penetrating, and agreeable acid taste, softened by a sweetish one. The pulp is frequently employed in medicine; it is cooling and gently laxative, and is peculiarly grateful in fevers and inflammatory diseases.

The largest and most elegant species is the *T. orientalis*, a native of Arabia, Persia, and the East Indies. The bark of *T. africana* is used in medicine as a tonic, and its ashes, like those of *T. gallica*, yield a large quantity of sulphate of soda.

**TAMUS**, *n.* A genus of plants, nat. order *Dioscoreaceae*. The *T. communis*, or common black bryony, is a very common plant in hedges and thickets throughout Europe, and is very frequent in England. It is a climbing herbaceous plant, having very large tubers and red berries. The whole plant contains a bitter acrid principle, which renders it unwholesome.

**TAN**, *v. t.* [*Fr. tanner*, to tan; *tanne*, a little black spot on the face; *It. tane*, tawny colour. *Gregoire*, in his *Armoric Dictionary*, suggests that this may be from *tan* or *dan*, which in *Leon* signifies an oak. But this is very doubtful. In *Ir. tianus* signifies a tan-house, and *tianonain*, is to drop or distil. *Spotting* is often from sprinkling, and *dyeing* from dipping. In *Gaelic*, *dean* is colour. It seems to be allied to *tawny*, and perhaps to *dun*.]

1. In the arts, to convert animal skins into leather by steeping them in an infusion of oak or some other bark, by which they are impregnated with tannin or tannic acid, an astringent substance which exists in several species of bark, and thus rendered firm, durable, and in some degree impervious to water.—2. It bears this name before and after it has been used. Tan, after being used in tanning, is used in gardening for making hot-beds; and it is also made into cakes and used as fuel. In some places, such cakes are commonly, but improperly, called *turf*; thus confounding it with peat fuel, which, however, it somewhat resembles.

**TANACETUM**, *n.* A genus of plants, nat. order *Compositae*, sub-order *Corymbiferae*. *T. vulgare*, or common tansy, is a well-known plant, being abundant in Britain, and throughout Europe, on the borders of fields and road sides. Every part of the plant is bitter, and it is considered as tonic and cordial, and has been administered in medicine in cases of worms and hysteria. The young shoots yield a green colouring-matter, used by the Finlanders for

## TANGENT

dyeing their cloth of that colour. It is said that if meat be rubbed with the fresh leaves, the flesh-fly will not touch it.

**TAN'AGRA**, } *n.* A genus of passerine

**TAN'GENT**, *n.* [*Fr. tangente; L. tangens*, touching. *See TOUCH.*] In *geom.*,

## TANGHIN

a straight line which touches or meets a circle or curve in one point, and which being produced, does not cut it. Euclid has shown, that the straight line drawn at right-angles to the diameter of a circle, from the extremity of it, is a tangent to the circle. In *trigonometry*, the tangent of an arc or angle is a straight line touching the circle of which the arc is a part, at one extremity of the arc, and meeting the diameter passing through the other extremity. Thus, in the figure let

AH be a straight line drawn touching the circle ADE at A, one extremity of the arc AB, and meeting the diameter IB produced, which passes through the other extremity B in the

point H; then AH is the tangent of the arc AB, or of the angle ACB, of which AB is the measure. The tangent of an arc or angle is also the tangent of its supplement. Thus, AII is the tangent of the supplement AI, or of the angle ACI; for it is easy to see, that the definition above

given applies equally to the arc AB and to the arc AI. The arc and its tangent have always a certain relation to each other; and when the one is given in parts of the radius, the other can always be computed by means of an infinite series. For trigonometrical purposes tangents for every arc from 0 degrees to 90 degrees, as well as sines, cosines, &c., have been calculated with reference to a radius of a certain length, and those or their logarithms formed into tables. In the higher geometry, the word tangent is not limited to straight lines, but is also applied to curves in contact with other curves, and also to surfaces.—*Metho*

*l of tangents*, the name given to the calculus in its early period. When the equation of a curve is given, and it is required to determine the tangent at any point, this is called the *direct method of tangents*; and when the sub-tangent to a curve, at any point, is given, and it is required to determine the equation of the curve, this is termed the *inverse method of tangents*. The above terms are synonymous with the differential and integral calculus.—*Tangent plane*, a plane which touches a curved surface; as a sphere, cylinder, &c.—*Natural tangents*, tangents expressed by natural numbers.—*Artificial tangents*, tangents expressed by logarithms.—*Line of tangents*, a line usually placed on the sector and Gunter's scale, by means of which the length of the tangent to any arc having a certain radius may be determined.—*Tangent screw*, a screw which acts in the direction of a tangent to an arc or circle. Such screws are used to adjust theodolites and other circular instruments. [*See WORM-WHEEL.*]

**TANGHINIA**, *n.* A genus of plants belonging to the nat. order Apocynaceae. *T. venenifera* is a tree which

*Tanghinia venenifera.*

**TAN'IST**, *n.* [Gaelic, *tannaiste*, a lord, the governor of a country; in Ireland, the heir apparent of a prince; probably from *tan*, a region or territory, or from the Gr. *δυναστεα*, a lord, which is from *δυνασαι*, to be powerful or able, the root of the Gaelic *duine*, a man. But both may be of one family, the root *tan*, *ten*, Gr. *τινα*, *L. teneo*, *W. tannu*, to stretch, strain, or hold.] Among the descendants of the Celts in Ireland, a lord, or the proprietor of a tract of land; a governor or captain. This office or rank was elective, and often obtained by purchase or bribery.

**TAN'ISTRY**, *n.* [Gaelic, *tanaisteachd*.] In Ireland, a tenure of lands by which the proprietor had only a life estate, and to this he was admitted by election. The primitive intention seems to have been that the inheritance should descend to the oldest or most worthy of the blood and name of the deceased. This was in reality giving it to the strongest, and the practice often occasioned bloody wars in families.

**TANK**, *n.* [Fr. *étang*, a pond; Sp. *estanque*; Port. *tanque*; Sans. *tanghi*; Japan, *tange*. This seems to be from the root of *stanch*, to stop, to hold.] A large basin or cistern; a reservoir for water or other fluids. Tanks are generally formed by making excavations in the earth, and lining the sides and bottom with bricks, stone, timber, cast-iron, or sheet-lead, or puddling them with clay. They are covered over, and used to collect and retain water and liquid manure, for domestic and agricultural purposes. In high mountainous pastures, tanks for collecting rain-water are indispensable to supply both men and cattle with water. The same name is sometimes applied to large open receptacles or ponds, formed by excavating the ground, and disposing the removed earth in the form of banks to retain the water.—2. In the navy, a case of sheet-iron for the stowage of the ship's water. It is generally about four feet square, and contains about two tons of water. Bilge tanks of various forms are also employed.

**TANK'ARD**, *n.* [Ir. *tancaird*; Gaelic, *tancard*; *tank* and *ard*.] A large vessel for liquors, or a drinking vessel, with a cover.

**TAN'NERY**, *n.* The house and apparatus for tanning.

**TAN'NIC ACID**, or **TAN'NIN**, *n.* A peculiar acid which exists in every part of all species of oak, especially in the bark, but is found in greatest quantity in gall-nuts. Tannic acid, when pure, is nearly white, and not at all crystalline. It is very soluble in water, and has a most astringent taste without bitterness. It combines with animal gelatine, forming an insoluble curdy precipitate, which has been called *tannogelatin*. It derives its name from its property of combining with the skins of animals, and converting them into leather, or *tanning* them. Its ultimate elements are 30 atoms of carbon, 18 of hydrogen, and 24 of oxygen. It is the active principle in almost all astringent vegetables.

**TAN'NIET**, *n.* One of the popular names of the *Arum esculentum*, an esculent root.

**TAN'NIN**, *n.* The name formerly applied to the tannic acid, before its acid character was known and understood.—*Artificial tannin*, the name given by Mr. Hatchett to a brown substance obtained by digesting powdered charcoal in nitric acid, and evaporating the solution. It has an astringent taste, and forms an insoluble compound with gelatine.

**TAN'NING**, *ppr.* Converting raw hides into leather.

**TAN'NING**, *n.* The practice, operation, and art of converting the raw hides and skins of animals into leather, by effecting a chemical combination between the gelatine of which they principally consist, and the astringent vegetable principle called *tannic acid*, or *tannin*. The object of the tanning process is, to produce such a chemical change in skins as may render them unalterable by those agents which tend to decompose them in their natural state; and in connection with the subsequent operations of currying, or dressing, to bring them into a state of pliability and impermeability to water, which may adapt them for the many useful purposes to which leather is applied. The larger and heavier skins subjected to the tanning process, as those of buffaloes, bulls, oxen, and cows, are technically called *hides*; while those of smaller animals, as calves, sheep, and goats, are called *skins*. After being cleared of the hair, wool, and fleshy parts, by the aid of lime, scraping, and other means, the skins are usually steeped in an infusion of ground oak bark, which supplies the

## TANTALUS'S CUP

astringent or tanning principle, and thus converts them into leather. Different tanners, however, vary much in the mode of conducting the process of tanning, and also the skins intended for different kinds of leather require to be treated differently. Various improvements have been made in the process of tanning, by which time and labour are much reduced, but it is found that the slow process, followed by the old tanners, produces leather far superior to that produced by quick processes.

**TAN'REC,** } *n.* The popular name of  
**TEN'REC,** } the several species of  
**TEN'DRAC,** } the insectivorous mam-  
malian genus *Centetes*, of which there

**TANTALIZATION,** *n.* The act of  
tantalizing.

**TANTALIZE,** *v. t.* [from *Tantalus*,  
in fable, who was condemned for his  
crimes to perpetual hunger and thirst,  
with food and water near him which  
he could not reach.] To tease or tor-  
ment by presenting some good to the  
view and exciting desire, but con-  
tinually frustrating the expectations  
by keeping that good out of reach; to  
tease; to torment.

Within themselves, have *tantaliz'd* thy life.

*hist.* a Lydian king who was con-  
demned to be plunged in water, with  
choice fruits hanging over him, with-  
out the power of reaching them, to  
satisfy his hunger or his thirst. Hence  
the English word *tantalize*.

**TANTALUS'S CUP,** *n.* A philosophi-  
cal toy. It consists of a siphon so  
adapted to a cup, that the short leg  
being in the cup, the long leg may go  
down through the bottom of it. When  
water is poured into the cup, it rises  
in the shorter leg of the siphon until it  
reaches up to the top of the bend of the

## TAPE

siphon, when it flows over into the  
longer leg, and escapes through the  
bottom of the cup, so  
that if water is not  
supplied to the cup as  
fast as it escapes by the  
siphon, the cup will  
soon be emptied. In  
the toy the siphon is  
concealed within the  
figure of a man, whose  
chin is on a level with  
the bend of the siphon.  
Hence, as soon as the  
water rises up to the  
chin of the image, it  
begins to subside, so  
that the figure, like Tantalus in the  
fable, is unable to quench his thirst.

speed.

of the preceding word as a nickname  
to a rustic country gentleman.] A  
devoted adherent of the court, in the  
time of Charles II.; a royalist; an  
opponent of the bill of Exclusion.

Those who took the king's side were

the verb to *tap* should follow the noun.]

or less tapered, portions of the threads  
being filed away in order to present a  
series of cutting edges. This being  
screwed into the nut in the manner of  
an ordinary bolt, forms the thread re-  
quired.

with gold and silver, representing  
figures of men, animals, landscapes, &c.,  
and used formerly for lining or cover-  
ing the walls of elegant apartments,  
churches, &c. The French ascribe  
the invention to the Saracens, but it  
was known among Eastern nations  
from a very remote era. A manufac-  
tory of tapestry was established at  
Paris in 1606 or 1607, which was con-  
ducted by Flemish artists; but the  
manufactory of the Gobelins, institu-  
ted in France under Louis XIV., be-  
came the most celebrated for the  
beauty and strength of the cloth, for  
elegance of design, and happy choice  
of colours. The finest paintings were  
copied, and eminent painters employed  
to furnish designs. In *painting*, ta-

[See TENIA.]

**TAPIO'CA**, *n.* A farinaceous substance prepared in South America, from the root of *Janipha*, or *Jatropha manihot*, the bitter Cassada or Manioc plant. This root presents the union of a deadly poison with highly nutritive qualities. The former appears to reside exclusively in the juice. In preparing cassava or manioc flour, the principal product yielded by the manihot, the roots, after having undergone the preliminary process of grating, &c., are subjected in bags to pressure in a screw press. The poisonous juice thus expressed, after being allowed to stand and settle for a short time, deposits a fine floury substance, which constitutes the tapioca of commerce. Tapioca is very nutritious and easy of digestion, being free from stimulating qualities. A spurious kind of tapioca is prepared from gum and potato flour.

**TAPIR**, *n.* A genus of pachydermatous, or thick-skinned mammals, of which three existing species, and several extinct ones, have been determined. The nose resembles a small fleshy proboscis; there are four toes to the fore feet, and three to the hind ones. The South American tapir, *T. Americanus*, is the size of a small ass, with a brown skin, nearly naked. The flesh is eaten. Another American species has been discovered in the Cordilleras, the back of which is covered with hair, and the bones of the nose more elongated, and approximating somewhat to the palæotherium. The *T. Malayanus*, or *indicus*, is found in the forests of Malacca

Fossil tapirs are scattered throughout Europe, and among them is a gigantic species, *T. giganteus*, Cuv., which in size must have nearly equalled the elephant.

Tar is soluble in alcohol, ether, and in the fixed and volatile oils. It consists of resin, empyreumatic oil, and acetic acid, or vinegar. There are numerous species and varieties of tares or vetches, many of which have been proposed to be introduced into general cultivation, but that which is found best adapted for agricultural purposes is the common tare, *Vicia sativa*, of which there are two principal varieties, the summer and winter tare. They afford excellent food for horses and cattle, and hence are extensively cultivated throughout Europe. [See VETCH.] The name *tare* is also given to two British leguminous plants of the genus *Ervum*, the *E. hirsutum*, or hairy tare, and *E. tetraspermum*, or smooth tare. sold in a cask, chest, bag, or the like, which the seller makes to the buyer on account of the weight of such cask, chest, or bag. Tare is distinguished into *real tare*, *customary tare*, and *average tare*. The first is the absolute weight of the package; the second, its supposed weight according to the practice among merchants; and the third is the medium tare deduced from weighing a few packages and taking it as the standard for the whole. In this country the prevailing practice, as to all goods that can be unpacked without injury, is to ascertain the real tare. Sometimes, however, the buyer and seller make a particular agreement about it. When the tare is deducted, the remainder is called the *nett* or *neat* weight.—*Tare and tret*, a rule in arithmetic by which the neat weight of a quantity of goods is ascertained, the gross weight and the allowances for the tare and the tret being given. The targum of the Pseudo-Jonathan, and the Jerusalem targum, are both on the Pentateuch, and are of considerable antiquity. The remaining six are comparatively modern. An endless variety of fancy tartans  
are now manufactured for ladies'  
dresses, some of wool, others of silk,  
others of wool and cotton, or of silk  
and cotton. The word *tartan* is sup-  
posed to be derived from the *Fr. tiretaine*, which signified a kind of  
linsey-woolsey anciently worn by the  
peasants of France, and which was  
most probably particoloured. The  
name, along with the manufacture

itself, seems to have been imported  
into Scotland from France or Germany.

**TARTAR'IC ACID**, *n.* The acid of  
tartar. It exists in grape juice, in  
tamarinds, and several other fruits;  
but principally in bitartrate of pot-  
ash, or cream of tartar, from which it  
is usually obtained. It crystallizes in  
large rhombic prisms, transparent and  
colourless, and very soluble in water.  
It is inodorous and very sour to the  
taste. A high temperature decom-  
poses it, giving rise to several new  
products. The solution of tartaric  
acid acts with facility upon those  
metals which decompose water, as  
iron and zinc; it combines readily with  
alkalies, earths, and metallic oxides,  
forming salts called *tartrates*. Tar-  
taric acid has a most remarkable dis-  
position to form double salts, as the  
tartrate of potash and soda or Rochelle  
salts; the tartrate of potash and anti-  
mony, or tartar-emetic. In a crystal-  
lized state it is composed of 8 atoms  
of carbon, 4 of hydrogen, 10 of oxygen,  
and 2 of water; and in its dry state it  
is composed of 8 atoms of carbon, 2 of  
hydrogen, and 8 of oxygen. Tartaric  
acid is largely employed as a discharge  
in calico-printing, and for making  
soda powders. In medicine it is used  
in small doses as a refrigerant.

The Dutch has *toetsen*, to touch, to try, to test; Dan. *taster* and, to attack or assault. This shows that the primary sense is to thrust or drive; allied perhaps to *dash*; hence to strike, to touch, to bring one thing in contact with another.] 1. A particular sensation excited in an animal by certain bodies, which are called *sapid*, applied to the tongue and palate, and moistened with saliva; as, the *taste* of an orange or an apple; a bitter *taste*; an acid *taste*; a sweet *taste*. This is the original and proper meaning of the word *taste*; but as the qualities of bodies which produce these sensations are unknown, they have obtained the names of the sensations themselves, by substituting the cause for the effect. We possess very few words to designate the endless variety of tastes, of which we are very sensible. Tastes have been divided into simple and compound, and philosophers have

## TASTEFULNESS

endeavoured to ascertain the number of each species.—3. The sense by which we perceive the relish of a thing. The organs of this special sense, are certain parts within the cavity of the mouth, obviously so disposed as to take early cognizance of matters about to be swallowed, and to act as sentinels for the remainder of the alimentary canal, at the entrance of which they are situated. They serve to give timely notice of any acid, caustic, or nauseous quality; of any undue temperature; of any inconvenient hardness, irregularity, size, or sharpness in the material submitted to them; and thus to protect the stomach against the intrusion of many hurtful agents. They, moreover, establish for our appetites a scale of liking and disliking. The organs of taste are confined to a portion of the tongue and a portion of the palate. The tip and sides of the tongue, and a small space at the root of it, together with a small surface at the anterior and superior part of the roof of the palate, are the only portions of surface in the cavity of the mouth and throat that can distinguish taste or sapidity from mere touch.—4. Intellectual relish, or discernment; as, he had no *taste* of true glory.

I have no *taste*

Of popular applause. Dryden.

*Note*.—In this use, the word is now followed by *for*. "He had no *taste* for glory." When followed by *of*, the sense is ambiguous, or rather it denotes experience, trial.—5. Judgment; discernment; nice perception, or the power of perceiving and relishing excellence in human performances; the faculty of discerning beauty, order, congruity, proportion, symmetry, or whatever constitutes excellence, particularly in the fine arts and belles lettres. Or it may be defined, that faculty of the mind by which we both perceive and enjoy whatever is beautiful and sublime in the works of nature and art, the perception of these two qualities being attended with an emotion of pleasure, distinguishable from every other pleasure of our nature. This faculty relishes some things, is disgusted with others, and to many is indifferent. *Taste* is not wholly the gift of nature, nor wholly the effect of art. It depends much on culture. It is the joint result of natural sensibility, of a good judgment, and an intimate acquaintance with the best productions of art. We say, a good *taste*, or a fine *taste*.—6. Style; manner, with respect to what is pleasing; the pervading air, the choice of circumstances, and the general arrangement in any work of art, by which taste in the artist or author is evinced; as, a poem or music composed in good *taste*.—7. a variety of figures, on the face and other parts of the body. This practice is very prevalent among the South-sea islanders, and the word *tattoo* appears to be formed by a reduplication of a Polynesian verb *ta*, meaning to strike, in allusion to the method of performing the operation. The instruments generally used in tattooing, among the south-sea Islanders, are edged with small teeth, somewhat resembling those of a fine comb. These are applied to the skin, and being repeatedly struck with a small mallet, the teeth make the incisions required, while the colouring tincture is introduced at the same time. In some cases, however, various instruments are employed, and the operation is very tedious and painful. Degrees of rank are indicated by the greater or less surface of tattooed skin. Some-

**TAX**, *n.* [*Fr. taxe*; *Sp. tasa*; *It. tassa*; from *L. taxo*, to tax. If from the *Gr. τὰξ*, *τασσω*, the root was *tago*, the sense of which was to set, to thrust on. But this is doubtful. It may be allied to *task*.] 1. A rate or duty, laid by government on the incomes or property of individuals, or on the products consumed by them; the produce of such duty or rate being placed at the disposal of government, for the public good. *Tax* is a term of general import, including almost every species of imposition on persons or property for supplying the public treasury, as tolls, tribute, subsidy, excise, impost, or customs. But more generally, *tax* is limited to the sum laid upon incomes, lands, houses, horses, cattle, professions, and occupations. So we speak of a land *tax*, an income *tax*, a window *tax*, a *tax* on carriages, &c. A *tax* may be either *direct* or *indirect*. It is said to

## TAXATION

be *direct*, when it is imposed on the incomes or property of individuals; and *indirect*, when it is imposed on the articles on which such incomes or property are expended. A tax may also be either *general* or *particular*; that is, it may either affect all classes indiscriminately, or only one or more classes. All taxes must ultimately be paid from the revenue of a country, or from its capital or stock. *Assessed taxes*, those duties imposed by government on windows, carriages, horses, dogs, men-servants, &c.—2. A sum imposed on individuals or on their property for local or civic purposes. Of this nature are county rates, taxes for the repair of roads or bridges, taxes for the support of the poor, usually called *poor rates*; borough tolls and dues; light dues, harbour dues; police taxes, &c. The *T. distichum*, or deciduous cypress, is a native of North America, where its wood is used for all the purposes to which timber is applied. The bark exudes a resin which is used by the negroes for dressing wounds.\* The roots are remarkable for the production of large conical knobs, hollow inside. **TAYLOR'S THEOREM**. In the *higher mathematics* a very elegant formula, of most extensive application in analysis, discovered by Dr. Brook Taylor, and published by him in 1715. It is to the following effect. Let *u* represent any function whatever of the variable quantity *x*; then if *x* receive any increment, as *h*, let *u* become *u'*; then we shall have  $u' = u + \frac{du}{dx} \cdot h +$

$$\frac{d^2 u}{d x^2} \cdot \frac{h^2}{1 \cdot 2} + \frac{d^3 u}{d x^3} \cdot \frac{h^3}{1 \cdot 2 \cdot 3} + \frac{d^4 u}{d x^4} \cdot \frac{h^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c., \text{ where } d \text{ represents the}$$

differential of the function *u*. The great value of this theorem was overlooked till it was made the basis of the differential and integral calculus, by Lagrange, in 1772.

difference between green and black tea is attained by means of some peculiarity in the manipulation during the process of manufacture. The black teas include *bohea*, *congou*, *souchong*, and *pehoo*; the green teas, *twankay*, *hyson-skin*, *young hyson*, *hyson*, *imperial*, and *gunpowder*. *Paraguay tea* is yielded by *Ilex paraguayensis*. The primary sense is to shoot out or extend.] 1. Two or more horses, oxen or other beasts, harnessed together to the same vehicle for drawing, as to a coach, chariot, waggon, cart, plough, and the like. It has been a great question whether teams of horses or oxen are most advantageously employed in agriculture. Wherever the land is only partially cultivated, and a portion of it remains in coarse pasture, which costs little or nothing to the occupier, or where extensive open commons afford cheap food for oxen, these ought to be employed in farm labour; but wherever arable land is the chief object of the farmer's attention, and the tillage of the soil is brought to any degree of perfection, horses should be employed. —2. Tears are the limpid fluid secreted by the lacrymal gland, and appearing in the eyes, or flowing from them. A tear, in the singular, is a drop or a small quantity of that fluid. Tears are excited by passions, particularly by grief. This fluid is also called forth by any injury done to the eye. It serves to moisten the cornea and preserve its transparency, and to remove any dust or fine substance that enters the eye and gives pain. Tears are a little heavier than water; they have a saline taste and an alkaline reactivity, owing to the presence of free soda. —2. Something in the form of a transparent drop of fluid matter; as gums or resins exuding in the form of tears from the eye.

*a*, Hooked scale of the Receptacle; *b*, Corolla all open.

cloth is manufactured, for the sake of the awns of the head, which are employed to raise the nap of woollen cloths. For this purpose the heads are fixed round the circumference of a large broad wheel or drum, so as to form a kind of brush. The wheel is made to turn round, while the cloth is held against the brush thus formed, and the fine hooked awn of the teasel readily insinuates itself into the woollen web, and draws out with it some of the fine fibres of the wool. These are afterwards shorn smooth, and leave the cloth with the fine velvet-like nap which is its peculiar appearance. Teasels, before being used, are sorted into *kings*, *middlings*, and *scrubs*, according to their size. Every piece of fine broad cloth requires from 1500 to 2000 teasels to bring out the proper nap, after which they are useless.

From the shape of its corolla, the plant has received the name of trumpet-flower. Teak timber is found to be excellent for ship-building, and has been called the oak of the East. It works easily, and though porous, is strong and durable; is easily seasoned, and shrinks but little; and from containing a resinous oil, it resists the action of water, as well as insects of all kinds. Besides being employed in ship-building, teak timber is extensively used in the East, in the construction of houses and temples. The tree which yields the African teak is not known. It belongs to the nat. order *Euphorbiacæ*.

**TEETH**, *plur.* of *Tooth*,—which see.—In the *teeth*, directly; in direct opposition; in front.

*Teeth*, or *cogs* of a wheel, in *mech.*, are projecting pieces which may be either formed on, or inserted into, the rim of a wheel which is intended to transmit motion from one axis to another, by the intervention of a similar wheel. The teeth being disposed at equal distances on the rims of both, when one wheel is turned its teeth enter successively the spaces between those of the other, thereby imparting motion to it. Toothed wheels are most frequently employed in machinery to transmit motion from one axis to another, and to regulate the relative velocities of two shafts; the larger one being termed the *wheel*, and the smaller the *pinion*. The velocities of revolution of every wheel and pinion which work in one another, have the same proportion as their number of teeth taken in a reverse order; so that by this means the relative velocities of wheels and pinions may be accurately determined according to any proposed rate, and consequently the relative velocities of the shafts which they turn. The teeth of wheels require to be formed with the utmost accuracy, according to certain mathematical curves, as that of the epicycloid, in order that the motion may be transmitted with the requisite smoothness and uniformity. [See **WHEEL**.]

**TEINDS**, *n.* plur. [Suio-Goth. *tiende*, the tenth part.] In *Scotch law*, the name for tithes. After the reformation, the whole teinds of Scotland were transferred to the crown, or to private individuals, called *titulars*, to whom they had been granted by the crown, or to *feuars*, or renters from the church, or to the original founding patrons, or to colleges or pious institutions. By a succession of decrees and enactments these tithes were generally rendered redeemable at a fixed valuation, but the clergy have now no right to the teinds beyond a suitable provision, called a stipend; so that teinds may now be described as that portion of the estates of the laity which is liable to be assessed for the stipend of the clergy. As a fund for the stipends of clergymen, teinds are under the administration of the court of session.—*Court of teinds*, a court in Scotland, otherwise called *Commissioners of teinds*. The powers conferred on this court are exercised by the judges of the court of session, as a parliamentary commission; but the court is distinct from the court of session, having a special jurisdiction, and a separate establishment of clerks and officers. Its jurisdiction extends to all matters respecting valuations and sales of

teinds, augmentations of stipends, prorogations of tacks, and of teinds, and (with consent of three-fourths of the heritors of the respective parishes) the disjunction or annexation of parishes, and the building of new churches, &c. An appeal lies from this court to the house of lords.

**TEIN'OSCOPE**, *n.* [Gr. *teino*, to extend, and *skopia*, to see.] The name given by Sir David Brewster to an optical instrument, formed by combining prisms of the same kind of glass in such a manner that the chromatic aberration of the light is corrected. **TEL'EGRAPH**, *n.* [Gr. *tele*, at a distance, and *graphein*, to write.] A machine for communicating intelligence from a distance by various signals or movements previously agreed on; which signals represent letters, words, or ideas which can be transmitted from one station to another, as far as the signals can be seen. The name *semaphore* is applied to some of the machines used for effecting telegraphic communication [see **SEMAPHORE**], and this term, in an extended signification, may be considered to embrace every means of conveying intelligence by gestures and visible signals, as flags, lanterns, rockets, blue lights, beacon fires, &c.; or by audible signals, as the firing of guns, the blowing of trumpets, the beating of drums, &c.; as well as by the machines called telegraphs or semaphores. For day signals the telegraph usually consists of a post of sufficient height, with two arms movable on the same pivot on the top of it, and a short arm, called the indicator, attached to one side of the upright post. The signals are made by varying the position of two arms, while the indicator shows the order or direction in which the signals are to be reckoned; that is, whether from right to left, or from left to right. To adapt the telegraph for night signals, a lantern is fixed to the pivot on which the arms move, and one is also attached to the extremity of each arm. In the management of a fleet at sea, telegraphic communication is indispensable. In the British navy, the signals are generally made by flags. The common or optical telegraph, which is always useless in hazy weather, is now superseded by the application of electricity or galvanism to the rapid communication of intelligence.—*Electric telegraph*, an apparatus for transmitting intelligence by means of voltaic electricity. Telegraphs of this kind are very various in the mechanical details of their construction; but they all depend on the electro-magnetic influence which a voltaic current is capable of exercising in its passage between the poles of the generating battery. The course

through which the current proceeds from, and returns to, the battery, is its *circuit*, and may be indefinitely prolonged by a conducting medium. A first and necessary, and, therefore, a general condition of the application of this agency to telegraphic purposes, consists consequently in the establishment of a connection between the telegraphic stations by at least one wire. This wire must likewise communicate at each extremity with an apparatus adapted to render the dynamical effects of the current visible in a definite and intelligible manner, and must likewise have communication with a voltaic generator. The common arrangement is such, that by turning a small handle at either station, complete metallic connection is obtained between the apparatus at the two stations, through the wire passing between them. The batteries are connected by wires with plates of metal at some depth in the ground, the moisture of which serves instead of a second wire to return the current to the generating battery. This circuit can be completed and broken, and the direction of the current reversed in the operation of telegraphing, by simply turning the handles before-mentioned; and the electric force, acting simultaneously on the apparatus at the respective stations, produces in them, in obedience to the will of the operator, those movements to which the species of mechanism is adapted, and which, having all preconcerted significations, are readily interpreted by the observer at the station to which the signals are transmitted. Those features are common to all electric telegraphs; and the signalling apparatus, though subject to indefinite variations of mechanical detail, is reducible to two modes of action, depending on the two fundamental laws of electro-magnetism. In the *needle-telegraph*, which is that most commonly employed in this country, the movements depend on the famous discovery of Ørsted (1819), that a magnet placed within the influence of a voltaic current is invested with an artificial polarity, and being freely poised, is deflected tangentially to the direction of the current, as exemplified in the galvanometer,—*which are*. The essential part of the apparatus, therefore, consists of a movable magnet placed within a coil of the circuit-wire: the axis of the magnet is horizontal, and, projecting through a dial-plate, carries a pointer to indicate the movements of the magnet concealed in the wire-coil behind the dial. So long as the circuit is *open*, the pointer remains in a vertical position, but the moment the circuit is *closed*, it is deflected to the right or left, according to the direction of the current, and as the circuit can be opened and closed, and the current reversed many times in a minute, a corresponding number of movements of the magnet, and, consequently, also of the pointer in front of the dial, can be effected, and all that is requisite to render these movements significant is an agreement as to the symbol which each position and combination of positions of the pointer shall indicate. And as the apparatus at each station is precisely a counterpart of that at the other, the movements in both are exactly alike, and the attendants see their respective pointers deflect ex-

## TELEGRAPH

actly in the same way, in the same direction, the same number of times, and virtually at the same instant. But there being only two kinds of movements afforded by the *single-needle-telegraph*, that is, a movement to the right and another to the left, it is usually necessary to combine repetitions of these to denote a single letter of the alphabet, and, therefore, the rate of telegraphing is slow. To obviate this, the *double-needle-telegraph* is employed. In this there are two coils of wire, two magnets, having each a pointer or index-hand visible in front of the dial-face, and two wires to convey the electric current and its message between the stations. The circuits are closed and opened, and the currents reversed, by two small handles which communicate with the mechanism behind the dial. These handles can be worked simultaneously, alternately, and in any order of succession, and all these movements and combinations of movements being indicated by the pointers and made to represent signals, the rapidity of telegraphing is much increased. The principle of action is, however, in every respect the same as in the single instrument; the passage of the impulse from station to station is equally instantaneous in both, but there being fewer movements of the handles necessary to produce a given number of signals, the rate of telegraphing is correspondingly greater with the double instrument. Both instruments also agree in having a bell, by which the attention of the attendant is called to the instrument when a message is about to be transmitted to him from the distant station. The bell is made to ring by an arrangement in which the second electro-magnetic law is brought into action, viz., that a galvanic current, passing through a wire twisted round a piece of soft iron, renders the iron powerfully magnetic, a property which it instantly loses when the current is stopped. The applications of this principle are exceedingly numerous; in the present case, the arrangement is such that the current causes the movement of a small lever connected with the bell-hammer, which accordingly strikes, and thereby gives the requisite notice to the attendant. A separate wire extends between the two stations, to connect these apparatus, and to allow of their being worked independently of the signalling instruments. The second class of electric telegraphs all depend fundamentally on the principle here brought into action. When the iron is magnetic, it exerts an attractive force on another piece of iron; and this force ceasing with the interruption of the current—which may take place many times in a minute—this second piece of iron receives a movement to and fro, according as the attracting force is created and destroyed. This alternation of movement being generated, there are abundant means of transforming it so as to indicate symbols; and, in some cases, it is successfully applied to record its own indications in a permanent form, at a minimum rate of 100 letters a minute. Even very promising attempts have been made to transmit fac-similes of printed and written documents and drawings by adaptation of this principle. Time is also telegraphed by ana-

## TELESCOPE

logous mechanism; and any number of clocks, at any distances apart, in the same voltaic circuit, may be worked synchronously with a standard clock. Telegraphs on the electro-magnetic principle may be indefinitely extended over a country, and may all be so connected one with another, that intelligence can be transmitted, through the same apparatus, from any number of stations with which it may be put in communication. The expense of their establishment consists chiefly in the connecting wires, which must necessarily be insulated from the ground, and protected against atmospheric influence. *Electric telegraphs* have of late years been brought into extensive use in this country, in the United States of America, and on the continent of Europe.

**TELEPHONIC**, *a.* [Gr. *τελε*, at a distance, and *φωνη*, sound.] Far-sounding; that propels sound to a great distance.

**TELESCOPE**, *n.* [Fr. from Gr. *τελεος*, end, or *τελε*, at a distance, probably the latter, and *σκοπος*, to see; It. and Sp. *telescopio*.] An optical instrument by which distant objects are brought within the range of distinct vision. The *terrestrial* telescope enables the mariner to survey the ocean to the limits of the horizon, and discovers to the traveller inaccessible objects and distant scenery lying around and beyond his line of route. The *celestial* telescope unfolds the wonders of the universe, and the science of astronomy has advanced with the gradual improvement of this instrument. The *modus operandi*, or law of action, by which the telescope assists human vision, is two-fold, and that under all the varieties of its construction. A distant object, viewed by the unaided eye, is placed in the circumference of a large circle, having the eye for its centre; and, consequently, the angle under which it is seen is measured by the minute portion of the circumference which it occupies. Now, when the distance is great, it is found that this angle is too small to convey to the retina any sensible impression—all the light proceeding from the object is too weak to affect the optic nerve. This limit to distinct vision results from the small aperture, or pupil, of the eye. The telescope substitutes its large object

## TELESCOPE

lens, or reflector, for the human eye, and consequently receives a quantity of light proportioned to its area or surface; hence, a distant point, imperceptible by the eye alone, is rendered visible by the aid of the telescope. The rays of light, after transmission or reflection, converge to a point, as they at first proceeded from a point; and thus an image of the object is formed, which, when viewed by the eye-piece, or lens, is more or less magnified. The telescope therefore assists the eye in these two ways: it gathers up additional light, and it magnifies the object—that is to say, its image. The *refracting* telescope is constructed of lenses alone, which, by successive refractions, produce the desired effect. This instrument was formerly very cumbersome and inconvenient, inasmuch as its length had to be increased considerably with every accession of power; and though the substitution of achromatic for ordinary lenses has rendered it more portable, its construction even at the present day does not enable it to compete with the reflecting telescope as an astronomical investigator. The *reflecting* telescope is composed of specula or concave reflectors, aided by a refracting eye-piece. To this instrument we owe the most wondrous discoveries in astronomical science. The names of Newton, Gregory, and Herschel are connected with its history; and in our own day, Lord Rosse has extended its powers as far, probably, as they can be carried with utility. The following diagrams exhibit the principles of construction and action in both sorts of telescopes.

Fig. 1

In fig. 1. A and B are two lenses of different focal lengths. Rays of light from a distant object falling upon the object-glass, A, are converged to a focus at C. The eye-glass, B, placed at its focal distance from the point of convergence, gathers up the diverging rays and carries them parallel to the eye. The magnifying power of the instrument is as AC : CB, or as the focal length of one lens to that of the other. In this construction the object is inverted by the intersection of the rays, and hence it is unsuitable for terrestrial purposes. To render the image erect, a more complicated eye-piece, consisting of two additional lenses, is necessary. Fig. 2. shows the structure

Fig. 2

of the reflecting telescope as constructed by Dr. Gregory. AB is a large speculum perforated in the centre; upon this fall the rays *a, b*, and *c, d*, which are reflected to convergence at *e*. A smaller speculum, C, takes up the diverging rays, and reflects them,

## TELL

slightly converging, through the aperture *o*, where they are received by a lens, and, after transmission, they intersect at *x*, and proceed to the eye-glass, whence they emerge parallel. The magnifying power of this instrument is great for its length, being

$$\text{as } \frac{o e}{e o} \times \frac{x C}{x o}.$$

The Herschelian telescope, invented by Sir William Herschel, is the one now generally used for astronomical purposes, as being the best and most powerful. In this construction there is no second speculum, and no perforation in the centre of the larger one placed at the bottom of the tube. The latter is fixed in an inclined position, so that the image formed by reflection falls near the lower side of the tube at its open end or mouth, where it is viewed directly by an eye-piece without greatly interfering with the light. This arrangement, in the case of large reflectors, is imposed by their great weight and difficult management; were it otherwise the ordinary construction would be preferred. The inclination of the speculum is a disadvantage.

[See **TALLY**.] The *tellers* of the exchequer were four in number; their duties were to receive money payable into the exchequer on behalf of the king, to give the clerk of the pells a bill of receipt for the money, to pay all money according to the warrant of the auditor of receipts, and to make weekly and yearly books of receipts and payments for the lord treasurer. The office was abolished by 4 and 5 Will. IV., c. 15, and the duties of the four tellers are now performed by a comptroller-general of the receipt and issue of the exchequer.—4. The ores are denominated *native*, *graphic*, *yellow*, and *black*. The native tellurium is of a colour between tin and silver, and sometimes inclines to a steel gray. The graphic tellurium is steel gray; but sometimes white, yellow, or lead gray. These ores are found massive or crystallized. Tellurium is very brittle, and has a specific gravity of 6.26. It is very fusible, and volatile at a red heat. It sometimes gives forth an odour of decayed horse-radish during combustion, which Berzelius ascribes to the presence of minute portions of selenium.

To mix so that one part qualifies the other; to bring to a moderate state; as, to *temper* justice with mercy.—2. To compound; to form by mixture; to qualify; as, by an ingredient; or, in general, to mix, unite, or combine two or more things so as to reduce the excess of the qualities of either, and bring the whole to the desired consistence or state.

**TEM'PERAMENT**, *n.* [Fr. from *L.* *temperamentum*.] 1. Constitution; state with respect to the predominance of any quality; as, the *temperament* of the body. In *physiol.*, temperament has been defined as a peculiar organization of the system common to several individuals, which to a certain extent influences the thoughts and actions. There is besides in each individual a further peculiarity of organization, which serves to distinguish his temperament from that of any other person, to whom, however, he may in other respects bear a great resemblance. This individual temperament is called an *idiosyncrasy*. The ancient physicians enumerated four temperaments, viz., the *sanguine*, the *choleric*, the *phlegmatic*, and the *melancholic*. Those terms are still in use among medical writers, and modern physiologists add a fifth, viz., the *nervous temperament*.—2. Medium; due mixture of different qualities.

The common law...has reduced the kingdom to its just state and *temperament*. *Hale.*

3. In music, temperament is the accommodation or adjustment of the imperfect concords in musical instruments, by transferring a part of their defects to the more perfect ones, to remedy in part the false intervals of instruments of fixed sounds, as the organ, harpsichord, piano-forte, &c. To those acquainted with the theory of the musical scale, it is well known that all the concords cannot be made perfect. The interval of a tone is not always the same; for instance, that lying between the fourth and fifth of the scale contains nine small parts called *commas*; whereas that between the fifth and the sixth of the major scale, contains only eight *commas*. Again, the diatonic semitone contains five *commas*, and the chromatic semitone three or four, according to the magnitude of the tone. These inequalities in the intervals of the scale are a source of imperfection in musical instruments whose sounds are fixed, and it is impossible altogether to

## TEMPERANCE

remedy the imperfection. If, for example, a piano-forte be tuned by a series of perfect octaves from the lowest C to the highest, and if another piano-forte be tuned from the same pitch by a series of perfect 5ths, ending

with B $\sharp$ , it will be found that this last note is not in tune with the upper C of the first piano-forte, being higher by a comma; but on the piano-forte B $\sharp$

being played on the same key as C, should be identically the same sound; therefore this discrepancy must be removed by a proper adjustment. Again, on the piano-forte three successive major thirds form an octave. Now, should these three successive thirds be tuned perfect to each other, it will be found that they fall short of the perfect octave by a comma, so that one, two, or all of the thirds must be altered and tuned sharper than perfect thirds, to compensate for the deficiency. Four successive minor thirds will, on the other hand, be found to exceed the octave by a comma, which defect must be removed by flattening. These slight alterations, which are made in order that any one of the twelve semitones which compose an octave may be fit to be used as a key note, without any shock to the ear, constitute what is termed the *temperament* of the scale; and the altered consonances are said to be *tempered*. There are in use two modes of temperament, the *equal* and the *unequal*. *Equal temperament* is that mode in which the necessary defects of the scale are distributed equally throughout it; and *unequal temperament*, that in which the defects are unequally distributed, so as to make some keys feel them less than others. The most common practice among tuners of the present day is to aim at equal temperament, but this is very difficult to accomplish; whereas the unequal temperament is easily obtained in tuning, and has the additional advantage of giving to every one of the twelve major and minor scales a particular character.

The harshness of a given concord increases with the *temperament*. *Prof. Fisher.* **TEMPERAMENTAL**, *a.* Constitutional. [*Not much used.*]

**TEM'PERANCE**, *n.* [Fr. from *L.* *temperantia*, from *tempero*.] 1. Moderation; particularly, habitual moderation in regard to the indulgence of the natural appetites and passions; restrained or moderate indulgence; as, *temperance* in eating and drinking; *temperance* in the indulgence of joy or mirth. *Temperance* in eating and drinking is opposed to *gluttony* and *drunkenness*, and in other indulgences, to *excess*.—2. Patience; calmness; sedateness; moderation of passion. He calm'd his wrath with goodly *temperance*. [*Unusual.*]

*Spenser.* *Temperance societies* are associations formed for the purpose of repressing drunkenness, and banishing it from society. The basis on which these associations have generally been formed, has been that of an engagement on the part of each member to abstain from the use of ardent spirits, except for medicinal purposes, and to forbear to provide them for the entertainment of friends or the supply of dependents. Many such associations exist in this country, and also in the United States

## TEMPERATURE

of America, and although considerable difference of opinion exists as to the soundness of the principle on which they are based, it must nevertheless be allowed by all that they have been productive of much good. They are, however, more appropriately designated *abstinence* or *abstinent societies*, than *temperance societies*. [See **ABSTINENCE**.]

**TEMPERANCE**, *a.* Belonging to temperance, or moderation in the use of strong drinks, almost or quite to the extent of abstinence; as, the *temperance movement*.

The *North temperate zone*, is the space included between the tropic of Cancer and the arctic circle; and the *South temperate zone*, that between the tropic of Capricorn and the antarctic circle. [See **ZONE**.]

**TEMPERATIVE**, *a.* Having the power or quality of tempering.

**TEMPERATURE**, *n.* [Fr. from L. *temperatura*.] 1. In *physics*, the state of a body with regard to heat or cold, as indicated by the thermometer, or generally by its effects on other bodies; or the degree of free caloric which a body possesses, when compared with other bodies. When a body applied to another, expands that body, we say it is of a *higher temperature*; that is, it possesses more free caloric. When it contracts another body, it is said to be of a *lower temperature*. Thus we speak of the *temperature* of air, of water, of a climate, &c.; two countries of the same *temperature*.—*Mean temperature of a place*, a mean of all the temperatures observed at that place at regular intervals during a certain space of time. The mean annual temperature of any place is obtained by taking a mean of all the temperatures indicated by the thermometer each day throughout the year. Springs in which the water does not considerably change its heat from one season of the year to another, afford an expeditious and accurate way of ascertaining the mean temperature of a place. Every place on the earth's surface has a mean temperature, which remains always nearly the same, and

## TEMPEST

which decreases from the equator to either pole, according to a certain law. The mean temperature at the equator is estimated at 81°. The temperature of a place depends not only on its latitude, but also on its elevation above the level of the sea, and various other local causes, such as the nature of the soil, the prevailing winds, the quantity of moisture, the electric state of the atmosphere, and the physical character of the adjacent countries and seas. But no cause has such an effect in lowering the temperature of a place as elevation above the level of the sea; and hence near the equator and tropics there are mountains which, owing to their great elevation, are covered with snow all the year round. [See **SNOW-LINE**.] The temperature of the sea is more uniform and moderate than that of the land. For ascertaining temperatures below 600° the thermometer is used, but for temperatures above 600°, instruments called pyrometers are employed.—2. Constitution; state; degree of any quality.

Memory depends upon the *consistence and temperature* of the brain. *Watts*.

3. Moderation; freedom from immoderate passions.

In that proud port, which her so goodly graceth,

Most goodly *temperature* you may descry. *Spenser*.

**TEMPERING**, *ppr.* Mixing and qualifying; qualifying by mixture; softening; mollifying; reducing to a state of moderation; hardening.

**TEMPERING**, *n.* The process of giving iron or steel, especially the latter, the different degrees of hardness required for the various purposes to which it is applied. The excellence of all cutting steel instruments depends on the degree of temper given to them. Different degrees of temper are indicated by different colours which the steel assumes. Thus, steel heated to 450°, and suddenly cooled, assumes a pale straw colour, and is employed for making razors and surgical instruments. [See **STEEL**.]

**TEMPEST**, *n.* [Fr. *tempête*; L. *tempestas*; Sp. *tempestad*; It. *tempesta*; from L. *tempus*, time, season. The primary sense of *tempus*, time, is a falling, or that which falls, comes, or happens, from some verb which signifies to fall or come suddenly, or rather to drive, to rush. *Time* is properly a coming, a season, that which presents itself, or is present. The sense of *tempest* is from the sense of rushing or driving. See **TEMERITY** and **TEMERARIOUS**.] 1. An extensive current of wind, rushing with great velocity and violence, and commonly attended with rain, hail, or snow; a storm of extreme violence. We usually apply the word to a steady wind of long continuance; but we say also of a tornado, it blew a *tempest*. The currents of wind are named, according to their respective degrees of force or rapidity, a *breeze*, a *gale*, a *storm*, a *tempest*; but *gale* is also used as synonymous with *storm*, and *storm* with *tempest*. *Gust* is usually applied to a sudden blast of short

pilgrims travelling to the Holy Land. The order originated with some persons who, in 1118, devoted themselves to the service of God, promising to live in perpetual chastity, obedience, and poverty, after the manner of canons. In 1228, this order was confirmed in the council of Troyes, and subjected to a rule of discipline. It flourished, became immensely rich, and its members became so insolent and vicious, that the order was suppressed by the council of Vienne, in 1312.—2. A student of the law.

tended, a seat; *temlu*, to form a seat, expanse, or temple; Gaelic, *teampul*.  
 1. A public edifice erected in honour of some deity. Among pagans, a building erected to some pretended deity, and in which the people assembled to worship. Originally, temples were open places, as the Stonehenge in England. In Rome, some of the temples were open, and called *acella*; others were roofed, and called *edes*. The most celebrated of the ancient pagan temples were that of Belus in Babylon, that of Vulcan at Memphis, that of Jupiter at Thebes, that of Diana at Ephesus, that of Apollo in Miletus, that of Jupiter Olympius in Athens, and that of Apollo at Delphi. The most celebrated and magnificent temple erected to the true God, was that built by Solomon in Jerusalem. The form most generally given to the ancient temples was that of a rectangle, but sometimes the construction was circular. Vitruvius divides temples into eight kinds, according to the arrangement of their columns, viz., temples in *antis* [see *ANTÆ*], *prostyle*, *amphiprostyle*, *peripteral*, *dipteral*, *pseudodipteral*, *hypæthral*, and *monopteral*. [See these terms.] In regard to intercolumniation, they were farther distinguished into *pycnostyle*, *systyle*, *eustyle*, *diastyle*, and *areostyle*. [See these terms.] Of circular temples there are two species, the *monopteral*, without a cell, and the *peripteral*, with a cell.—In *Scripture*, the tabernacle is sometimes called by this name; 1 Sam. i.—iii.—2. On the site of both, modern edifices have been erected, those in London forming the two Inns of Court, called the Middle Temple and Inner Temple.

The degrees of time, generally speaking, are five, and are designated by the terms *largo*, *adagio*, *andante*, *allegro*, and *presto*; and the intermediate degrees are expressed by additions to these terms. A *tempo*, denotes that the former time is to be resumed, or a more distinct time observed.

particles, so that they resist any effort

to pull or force them asunder. Iron

and steel are the most *tenacious* of all

known substances.

**TENACIOUSLY**, *adv.* With a disposition

to hold fast what is possessed.—

2. Adhesively; with cohesive force.—

3. Obstinately; with firm adherence.

**TENACIOUSNESS**, *n.* The quality of

holding fast; unwillingness to quit,

resign, or let go; as, a man's *tenacious-*

*ness* of his rights or opinions.—2. Ad-

hesiveness; stickiness; as, the *tena-*

*ciousness* of clay or glue.—3. Retentive-

ness; as, the *tenaciousness* of memory.

—4. In *physics*, the same as *tenacity*,

but less used. [See **TENACITY**.]

**TENACITY**, *n.* [*Fr. tenacité*; *L.*

*tenacitas*, from *teneo*, to hold.] 1. Ad-

hesiveness; that quality of bodies which

makes them stick or adhere to others;

glutinousness; stickiness; as, the

*tenacity* of oils, of glue, of tar, of

starch, and the like.—2. In *physics*,

that property of material bodies by

which their parts resist an effort to

force or pull them asunder; cohesive

force; in common language, toughness.

It is opposed to *brittleness*, or *fragility*.

Tenacity results from the attraction

of cohesion which exists between the

particles of bodies, and the stronger

this attraction is in any body, the

greater is the tenacity of the body.

Tenacity is consequently different in

different materials, and in the same

material it varies with the state of the

body in regard to temperature and

other circumstances. The tenacity of

different kinds of wood and metal is

ascertained by taking rods of them,

fixing these immovably at one end, and

finding what weight suspended at the

other is sufficient to overcome the

cohesive force, and break or pull

asunder the rods; the weights being

considered as the measures of tenacity

in the different kinds of materials. Of

the different kinds of wood the most

tenacious is fir; but of all substances,

iron and steel are the most tenacious,

and steel much more so than iron. The

tenacity of iron is a subject of the

greatest importance, as the stability

and strength of suspension bridges

depend upon it.

**TENACULUM**, *n.* [from *L. teneo*, to

hold; to seize.] A surgical instrument

for seizing and drawing out the mouths

of bleeding arteries in operations, so

that they may be secured by ligaments.

For this purpose it has a hooked ex-

trinity with a fine sharp point.

**TENAIL**, } *n.* [*Fr. tenaille*, from

**TENAILLE**, } *tenir*; *L. teneo*, to hold.]

In *fort.*, an outwork or rampart raised

in the main ditch, immediately in front

of the curtain, between two bastions.

In its simplest form, it consists of two

faces forming with each other a re-

entering angle; but generally it con-

sists of three faces forming two re-

entering angles, in which case it is

called a *double tenaille*. Any work

belonging either to permanent or field

fortification, which, on the plan, con-

sists of a succession of lines forming

salient and re-entering angles alter-

nately, is said to be à *tenaille*. [See

**RAVELIN**.]

**TENAILLON**, *n.* In *fort.*, *tenaillons*

are works constructed on each side of

the ravelins, like the lunettes, but

differing in this, that one of the faces

of the *tenaillon* is in the direction of

the ravelin, whereas that of the lunette

is perpendicular to it. Works of this

kind, however, are seldom adopted.

**TENANCY**, *n.* [*Sp. tenencia*; *Fr.*

*tenant*; *L. tenens*.] In *law*, a holding

or possession of lands or tenements

from year to year, for a term of years,

for a life or lives, or at will; tenure;

as, *tenancy* in fee simple; *tenancy* in

tail; *tenancy* by the courtesy; *tenancy*

at will. *Tenancy* in common happens

where there is a unity of possession

merely.

**TENANT**, *n.* [*Fr. tenant*, from *tenir*, to

978

hold; *L. teneo*; *Gr. tenuo*, to strain, stretch, extend; *W. tannu*, to stretch; *tynu*, to pull; *tyn*, a stretch; *ten*, drawn; *It. tenere*; *Sp. tener*, to hold.]

1. A person who holds or possesses

lands or tenements by any kind of

title, either in fee, for life, for years,

or at will. The word in English law

is used with several additions. Thus,

*tenant in dower*, is she that possesses

*the courtesy*, he that holds for his life,

by reason of a child begotten of him

by his wife, being an heiress; *tenant in*

*mortgage*, he that holds by means of a

mortgage; *tenant by the verge in ancient*

*demesne*, one who is admitted by the

rod in the court of ancient demesne.

[See **VERGE**.]—*Tenant by copy of*

*court roll*, one who is admitted tenant

of any lands, &c., within a manor;

*tenant in fee simple*, one who has lands

or tenements to hold to him and his heirs

for ever; *tenant in fee-tail*. [See **TAIL**.]

*Tenant at will*, is where lands or tenements

are let by one man to another, to

have, and to hold to him at the will

of the lessor, by force of which letting

the lessee is in possession, but the

lessor may put him out at whatever

time he pleases; *tenant from year to*

*year*, is where one lets lands or tenements

to another without limiting any

certain or determinate estate; *tenant*

*by lease*. [See **LEASE**.] *Tenant upon*

*sufferance*, he who enters by lawful

lotting or title, and afterwards wrong-

fully continues in possession; *joint-*

*tenants* are such as have equal rights

in lands and tenements by virtue of

one title; *tenants in common*, those who

have equal rights, but held by diverse

titles. The word *tenant*, in the most

ordinary acceptation, signifies one who

holds lands or houses under another, to

whom he is bound to pay rent, and

who is called his landlord. In *Scotland*,

the term *tenant* is used only for the

lessee or party to whom a lease is

granted.—2. One who has possession

of any place; a dweller.

The happy *tenant* of your shade. *Cowley.*

*Tenant in capite*, or *tenant in chief*, by

the laws of England, is one who holds

immediately of the king. According

to the feudal system, all lands in Eng-

land are considered as held immediately

or mediately of the king, who is styled

lord paramount. Such tenants, how-

ever, are considered as having the fee

of the lands and permanent possession.

**TENANT**, *v. t.* To hold or possess as

a tenant.

Sir Roger's estate is *tenanted* by persons

who have served him or his ancestors.

Tench (*Tinca vulgaris*).

tench is remarkable for its tenacity of life; it is readily distinguished from the carp by the small size of its scales, and also the small extent of the dorsal fin. Tenches are in great repute as delicious and wholesome food.

In practice it generally consists in an offer to pay money on behalf of a party indebted, or who has done some injury to the creditor or to the party injured. To constitute a legal tender, such money must be offered as the law prescribes.

A tender to the amount of 40s. may be made in silver; but beyond that amount it must be made in gold. If a tender be made of a larger amount in silver or in bank notes, and no objection be taken at the time to the medium in which it is made, the tender will be held good to the full amount to which it is made. There is also a tender of issue in pleadings, a tender of an oath, &c. In an action of damages in *Scots law*, a tender is a judicial offer made by the defender, of a specific sum in name of damages, and of expenses down to the date of the tender.—5. The three species are found in Madagascar, and the first, which is the Tenrec, properly so called, and the largest, is naturalized in the Isle of France.

**TEN'DRIL**, *n.* [Fr. *tendrillon*, from *tenir*, to hold.] A filiform spiral shoot of a plant that winds round another body for the purpose of support. *Tendrils* or *cirri*, are only found on those plants which are too weak in the stem to enable them to grow erect; they twist themselves in a spiral form around other plants or neighbouring bodies, and thus the plants on which they grow are enabled to elevate themselves. In most cases, tendrils are prolongations of the petioles; but in some cases they are altered stipules, as in the cucumber, and in other cases they are transformed branches or flower-stalks; as in the vine.

The compass of the *tenor* is from C, the second space in the bass, to G, the second line in the treble. Hence, the *tenor* and *treble* are reciprocally at the distance of an octave.—5. The persons who sing the *tenor*, or the instrument that plays it, which latter is a larger sort of violin. *Tenor-claf*, the C clef, placed on the fourth line, for the use

In *English law*, the manner of holding lands and tenements of a superior, or the feudal relation which subsists between lord and vassal in respect of lands and tenements. All land is held of the king, either mediately or immediately; and ultimately all land is held of the king. The ownership of land is therefore never unlimited as to extent, for he who is the owner of land in fee, which is the largest estate that a man can have in land, is not absolute owner: he owes services in respect of his fee (or fief), and the seignory of the lord always subsists. All land in the hands of any layman is held of some lord, to whom the holder or tenant owes some service; but in the case of church lands, although they are held by tenure, no temporal services are due, but the lord of whom these lands are held must be considered the owner, although the

beneficial ownership can never revert to the lord. All the species of ancient tenures may be reduced to four, three of which subsist to this day. 1. A syllogism consists of three terms, the major, the minor, and the middle. The predicate of the conclusion is called the major term, because it is the most general, and the subject of the conclusion is called the minor term, because it is less general. that is, either a half statue, or bust, not placed upon, but incorporated with, and, as it were, immediately springing out of, the square pillar, which serves as its pedestal. The pillar part is generally made to taper downwards, or made narrower at its base than above. **TERMITES**, } *n.* a family of neu-  
**TERMITIDÆ**, } ropterous insects,  
known by the name of white ants. It includes the genus *Termes*, Linn. These insects have little affinity with the true ants, although they resemble them in their mode of life. They are chiefly confined to the tropics; and are found very plentifully in western Africa; they unite in societies, each composed of an immense number of individuals, living in the ground and in trees, devouring all vegetable and animal substances within their reach, and often attacking the wood-work of houses. The white ants build their dwellings in the ground, in the form of pyramids or cones, ten or twelve feet high, resembling native villages in extent, and for which indeed they may readily be mistaken. These dwellings, which are so firmly cemented as to be capable of bearing the weight of three or four men, are divided off into several apartments as magazines, chambers, galleries, &c. When assaulted, the ants make their attack and defence with system and desperate courage. After impregnation, the abdomen of the female extends to an enormous size, exceeding the rest of her body nearly 2000 times; in which state it is filled with an immense number of eggs, protruded to the amount of about 8000 in 24 hours.

*Termites helioceus.*

- a.* Larva or worker; } Natural size.  
*b.* Pupa or soldier; }  
*c.* Perfect winged insect reduced in size.

On emerging from the egg, the insects, in their larva state, are furnished with a great hard head and strong toothed jaws, but destitute of eyes. These are the labourers, *a*, who, although not more than a quarter of an inch long, build their edifices, procure provisions for the community, and take care of the eggs. On changing to the pupa state, *b*, they become larger and more powerful; the head is nearly as big as the body, while the jaws project beyond the head, and are very sharp, but without teeth. They now become soldiers and never work themselves, but superintend the labourers, and act as guards to defend the common habitation from violence and intrusion. The next change brings the pupæ or soldiers to their perfect state, as male or female winged insects, *c*. These emerge into the air during the night, or on a damp and cloudy day; in a few hours, however, the solar heat causes their wings to wither and become dry; the insects then fall to the ground, and are eagerly sought after by hosts of birds, lizards, and even negroes themselves, who roast and eat them.

differ from the *crustacea* in their composition, the calcareous part of the shells of testacea being carbonate of lime, whereas in the shells of *crustacea* it is phosphate of lime. The testacea also retain their shells as long as they live; the *crustacea* cast them annually, or at least periodically. The term testacea is applied by Cuvier to an order of his class *Acephala*. [See VERMES.]

The primary sense of *testa*, *testis*, *testor*, &c., is to thrust or drive; hence the sense of hardness, compactness, in *testa* and *testis*; and hence the sense of attest, contest, detest, *testator*, *testament*, all implying a sending, driving, &c.] Pertaining to shells; consisting of a hard shell, or having a hard continuous shell. *Testaceous animals* are such as have a strong thick entire shell, as oysters and clams; and are thus distinguished from *crustaceous animals*, whose shells are more thin and soft, and consist of several pieces jointed, as lobsters.—*Testaceous medicines*, are all preparations of shells and like substances, as the powders of crabs' claws, pearl, &c.

**TESTAMENT**, *n.* [Fr. from L. *testamentum*, from *testor*, to make a will.] 1. A solemn authentic instrument in writing, by which a person declares his will as to the disposal of his estate and effects after his death. This is otherwise called a *will*, but in strictness of language, the term *will* is limited to land, and *testament* to personal estate. A *testament*, to be valid, must be made when the testator is of sound mind, and it must be written, subscribed, &c., in such manner as the law prescribes. In *Scots law*, the word *testament*, in the strictly legal acceptance, signifies a deed in writing, by which the grantor appoints an executor, that is, a person to administer his movable estate after his death, for the behoof of all who may be interested in it. A *testament* may thus consist merely of the nomination of an executor, or it may contain, along with such a nomination, clauses bequeathing, in the form of legacies, either the whole or part of the movable estate. In its more common meaning, however, a *testament* is a declaration of what a person wills to be done with his movable estate, after his death. Any person has power to execute an effectual *testament* who is of sound mind at the time, although he be labouring under bodily sickness, or even be on death-bed. A *testament* is effectual only with regard to the movable estate of the testator, and even in regard to things strictly movable, a person cannot dispose by *testament* of more than

## TESTIFICATOR

that share of them which is termed the dead's part; he must not encroach upon the *jus relictæ*, or *legitim*. [See *these terms*.] A *testament* may be revoked at any time during the life of the testator. All *testaments* containing the nomination of an executor, or the bequest of a legacy of greater value than £100 Scots, must be in writing, and properly tested and signed before witnesses, but if it be in the testator's own handwriting, witnesses are not required. [For more information respecting *testaments* and *wills* in English and Scots law, see *WILL*. See also *NUNCUPATIVE*.]—2. The name of each general division of the canonical books of the sacred Scriptures; as, the Old *Testament*; the New *Testament*. The black cock (*Tetrao tetrix*); the red grouse (*Lagopus scoticus*); and the common ptarmigan (*Lagopus mutus*) are British species. # THANK

**THANAGE**, *n.* The land granted to a thane; the district in which the thane anciently presided.

**THANE**, *n.* [Sax. *thegn*, *thegn*, a minister or servant; *thegnian*, *thenian*, to serve; D. and G. *dieneu*, to serve; Sw. *tjena*, to serve; *tjenare*, a servant; Dan. *tiener*, to serve; *tiener*, a servant.] In early *Eng. hist.*, a title of honour belonging to the Anglo-Saxon nobility. In its original meaning, it signified a minister or honourable retainer, and was applied to the followers of kings and chieftains. The thanes in England were formerly persons of some dignity; of these there were two orders, the king's thanes, who attended the Saxon and Danish kings in their courts, and held lands immediately of them; and the ordinary thanes, who were lords of manors, and who had a particular jurisdiction within their limits. In a later age of the Anglo-Saxon power, the term *thane* seems to have been applied to all landed proprietors who were below the rank of earl, and above that of alderman, and had the privilege of assisting in framing the laws. The rank of thane implied the possession of a certain amount of landed property, and five hides of land is supposed to have been the amount required for a thane of the highest order. After the Conquest, this title was disused, and *baron* took its place. In *Scotland*, *thane* was a recognised title down to the end of the 15th century, and it appears to have implied from the first a higher dignity than in England, and to have been, for the most part, synonymous with *earl*, which title was generally annexed to the territory of a whole county.

**THANEDOM**, *n.* The property or jurisdiction of a thane.

**THANE-LANDS**, *n.* Lands granted to thanes.

**THANESHIP**, *n.* The state or dignity of a thane; or his seignory.

**THANK**, *v. t.* [Sax. *thancian*; G. and D. *dankeu*; Ice. *thacka*; Sw. *tacka*; Dan. *takker*.] We see by the Gothic dialects that *n* is not radical. To ascertain the primary sense, let us attend to its compounds; G. *abdankeu*, [which in English would be *off-thank*,] to dismiss, discharge, discard, send away, put off, to disband or break as an officer; *verdanken*, to owe or be indebted; D. *afdankeu*, to cashier or discharge. These senses imply a sending. Hence, *thank* is probably from the sense of giving, that is, a render or return.] 1. To express gratitude for a favour; to make acknowledgments to one for kindness bestowed.

We are bound to thank God always for you; 2 Thess. i.

Jonah bowed himself and thanked the king; 2 Sam. xiv.

2. It is used ironically. Weigh the danger with the doubtful bliss, And thank yourself, if aught should fall amiss. Dryden.

**THANK**, } *n.* generally in the plural.

The species are known under the name deadly carrot, and are mostly inhabitants of the countries of the Mediterranean. They are perennial herbs, with doubly or trebly pinnate leaves, large compound umbels, and yellow flowers. The roots possess acrid and corrosive properties. The root of *T. villosa*, when applied to the skin, causes inflammation and vesication.—*T. silphium*, a native of the north of Africa, is supposed to be the plant which produced the juice called *Silphium*, which was much prized by the ancients.

**THAR**, *n.* A species of antelope.

**THARM**, *n.* [Sax. *thearm*; G. and D. *darm*.] Intestines twisted into a cord. [Local.]

**THAT**, an adjective, pronoun, or substitute. [Sax. *that*, *that*; Goth. *thata*; D. *dat*; G. *das*. Qu. Gr. *ταυτα*.] This word is called, in Saxon and German, an article, for it sometimes signifies *the*. It is called also, in Saxon, a pronoun, equivalent to *id*, *istud*, in Latin. In Swedish and Danish it is called a pronoun of the neuter gender. But these distinctions are groundless and of no use. It is probably from the sense of setting. 1. *That* is a word used as a definitive adjective, pointing to a certain person or thing before mentioned, or supposed to be understood. "Here is *that* book we have been seeking this hour." "Here goes *that* man we were talking of."

It shall be more tolerable for Sodom and Gomorrah in the day of judgment, than for *that* city; Matt. x.

2. *That* is used definitively, to designate a specific thing or person emphatically.

The woman was made whole from *that* hour; Matt. ix.

In these cases, *that* is an adjective. In the two first examples, the may be substituted for it. "Here is the book we have been seeking." "Here goes the man we were talking of." But in other cases, *the* cannot supply its place, and *that* may be considered as more emphatically definitive than *the*.—3. *That* is used as the representative of a noun, either a person or a thing. In this use it is often a pronoun and a relative. When it refers to persons, it is equivalent to *who*, and when it refers to a thing, it is equivalent to *which*. In this use, it represents either the singular number or the plural.

He *that* reproveth a scorner, getteth to himself shame; Prov. ix.

They *that* hate me without a cause, are more than the hairs of my head; Ps. lxi.

A judgment *that* is equal and impartial, must incline to the greater probabilities.

They shall gather out of his kingdom all things *that* offend; Matt. xiii.

4. *That* is also the representative of a sentence or part of a sentence, and often of a series of sentences. In this case, *that* is not strictly a pronoun, a word standing for a noun; but is, so to speak, a *pro-sentence*, the substitute for a sentence, to save the repetition of it.

And when Moses heard *that*, he was content; Lev. x.

*That* here stands for the whole of what Aaron had said, or the whole of the preceding verse.

I will know your business, *that* I will.

Ye defraud, and *that* your brethren; 1 Cor. vi.

*That* sometimes in this use, precedes the sentence or clause to which it refers.

*That* be far from thee, to do after this manner, to slay the righteous with the wicked; Gen. xviii.

*That* here represents the clause in italics.—5. *That* sometimes is the substitute for an adjective. You allege that the man is *innocent*; *that* he is not.—6. *That*, in the following use, has been called a conjunction. "I heard that the Greeks had defeated the Turks." But in this case, *that* has the same character as in No. 4. It is the representative of the part of the sentence which follows, as may be seen by inverting the order of the clauses.

"The Greeks had defeated the Turks; I heard *that*." "It is not *that* I love you less." *That* here refers to the latter clause of the sentence, as a kind of demonstrative.—7. *That* was formerly used for *that which*, like *what*.

We speak *that* we do know, and testify *that* we have seen; John iii.

[This use is no longer held legitimate.]—8. *That* is used in opposition to *this*, or by way of distinction.

If the Lord will, we shall live, and do *this* or *that*; James iv.

9. When *this* and *that* refer to foregoing words, *this*, like the Latin *hic* and French *ceci*, refers to the latter, and *that* to the former. It is the same with *these* and *those*.

*Self-love* and *reason* to one end aspire, Pain their aversion, pleasure their desire; But greedy *that*, its object would devour, *This* taste the honey, and not wound the flower.

10. *That* sometimes introduces an explanation of something going before. "Religion consists in living up to those principles; *that* is, in acting in conformity to them." Here *that* refers to the whole first clause of the sentence.

—11. "Things are preached, not in *that* they are taught, but in *that* they are published." Here *that* refers to the words which follow it. So when *that* begins a sentence. "That we may fully understand the subject, let us consider the following propositions."

*That* denotes purpose, or rather introduces the clause expressing purpose, as will appear by restoring the sentence to its natural order. "Let us consider the following propositions, *that*, [for the purpose expressed in the following clause,] we may fully understand the subject." "Attend *that* you may receive instruction." Here also *that* expresses purpose elliptically; "Attend for the purpose *that* you may receive instruction;" *that* referring to the last number. This elliptical use of *that* is very frequent; the preposition for being understood. "A man travels *that* he may regain his health." He travels for *that* purpose, he may regain his health. The French often retains the preposition in such cases, *pour que*. "Do all things without murmurings and disputings, *that* ye may be blameless and harmless;" Phil. ii. 14. Do all things without murmurings, for *that* purpose; to *that* effect, ye may be blameless.—In *that*, a phrase denoting consequence, cause, or reason; *that* referring to the following sentence.

**THATCH**, *n.* [Sax. *thac*, connected with *theccan*, *thecan*, to cover; L. *tego*, Eng. *deck*; G. *dach*, a roof; D. *dak*; Sw. *tak*; Dan. *tag*, *tæhke*; Gaelic, *tuyhe*, *tuyhe*. The primary sense is to put on, to spread over or make close.] Straw, rushes, reeds, heath, &c., used to cover the roofs of buildings, or stacks of hay or grain, for securing them from rain, &c.

**THATCH**, *v. t.* To cover with straw, reeds, or some similar substance; as, to *thatch* a house or a stable, or a stack of grain.

**THATCH'ING KNIFE**, *n.* An implement used in thatching houses for trimming the eaves.

**THAUGHTS**, *n.* [A corruption of *Thwarts*.] The benches of a boat on which the rowers sit. [See *THWART*.]

**THAUMATROPE**, *n.* [Gr. *θαυμα*, a wonder, and *τροπε*, to turn.] An optical toy contrived by Dr. Paris, the principle of which depends on the persistence of vision, or on the well-known fact, that when a person whirls a burning stick rapidly round, a complete circle of light is seen marking out the path described by the burning end. It consists of a circular card, having two silk strings fixed to it at the extremities of a diameter. By twisting the silk strings with the finger and thumb of each hand, it may be twirled round with considerable rapidity. On one side of the card there is drawn any object, such as a chariot, and on the other, the charioteer in the attitude of driving, so that when the card is twirled round, the charioteer is seen driving the chariot.

**THAUMATUR'GIC**, or **THAUMATUR'GICAL**, *a.* [See *THAUMATURGY*.] Exciting wonder.

**THAUMATUR'GIST**, *n.* One who **THAUMATUR'GUS**, *n.* One who deals in wonders, or believes in them. It is sometimes used by Roman Catholics to signify a miracle-worker; as Gregory *Thaumaturgus*.

**THAUMATURGY**, *n.* [Gr. *θαυμα*, a wonder, and *εργον*, work.] The act of performing something wonderful.

**THAW**, *v. i.* [Sax. *thawan*; G. *thauen*; Dan. *toer*; Sw. *töa*; Gr. *ταυω*.] 1. To melt, dissolve, or become fluid, as ice or snow. [It is remarkable that this word is used only of things that congeal by frost. We never say, to *thaw* metal of any kind.]—2. To become so warm as to melt ice and snow; used of weather.

**THAW**, *v. t.* To melt; to dissolve; as ice, snow, hail, or frozen earth.

**THAW**, *n.* The melting of ice or snow; the resolution of ice into the state of a fluid; liquefaction by heat, of any thing congealed by frost.

**THAW'ED**, *pp.* Melted, as ice or snow.

**THAW'ING**, *ppr.* Dissolving; resolving into a fluid; liquefying; as, any thing frozen.

**THE**, an adjective, or definitive adjective. [Sax. *the*; D. *de*. Qu. Ch. *ἡ, da*.] 1.

This adjective is used as a definitive, that is, before nouns which are specific or understood; or it is used to limit their signification to a specific thing or things, or to describe them; as, the laws of the twelve tables. The independent tribunals of justice in our country, are *the* security of private rights, and the best bulwark against arbitrary power. *The* sun is the source of light and heat.

This he calls *the* preaching of the cross. *Simon*.

2. *The* is also used rhetorically before a noun in the singular number, to denote a species by way of distinction; a single thing representing the whole. *The* fig-tree putteth forth her green figs; *the* almond-tree shall flourish;

## THEATINS

the grasshopper shall be a burden.—3. In poetry, the sometimes loses the final vowel before another vowel.

*Th'* adorning thee with so much art.  
Is but a barbaous skill. Cowley.

4. *The* is used before adjectives in the comparative and superlative degree. *The longer we continue in sin, the more difficult it is to reform. The most strenuous exertions will be used to emancipate Greece. The most we can do is to submit; the best we can do; the worst that can happen. The* is generally pronounced with the *e* short; but when used emphatically, it is pronounced as *thee*.

**THE'A**, *n.* [See **TEA**.] A genus of plants, nat. order Ternstroemiaceæ, which includes the plants yielding the tea of commerce. The species are few, at most three, *T. viridis*, *T. bohea*, and *T. assamica*, and some botanists assert that even these are varieties of a single species. *T. viridis* is a large,

*Thea viridis.*

hardy, evergreen plant, with spreading branches, its leaves three to five inches long, thin, very broadly lanceolate, light green and wavy, with large and irregular serratures, the flowers large, usually solitary, and of a white colour. It is found both in China and Japan. *T. bohea* is a smaller plant than *T. viridis*, and differs from it in several particulars. From either species, however, by means of a different process of manipulation in the manufacture, both black and green tea are produced. Tea is cultivated in China over a great extent of territory; it is also extensively cultivated in Japan, Tonquin, Cochinchina, and Assam. In China, the climate most congenial to it seems to be that between the 27th and 31st degree of north latitude. In the husbandry of China, the tea-plant may be said to take the same place which the vine occupies in the southern countries of Europe. Its growth is chiefly confined to hilly tracts, not suited to the growth of corn, and the rearing of it requires great skill and attention, as well as the preparation of the leaves. [See **TEA**.]

**THEAN'DRIC**, *a.* [Gr. *Θεός*, God, and *άνθρωπος*, a man.] Designating the union of divine and human operation in Christ, or the joint agency of the divine and human nature.

**THEARCHY**, *n.* [Gr. *Θεός*, God, and *αρχή*, rule.] Government by God; more commonly called *Theocracy*.

**THEATINS**, *n.* An order of monks  
**TEATINS**, *n.* founded at Rome in

## THEATRIC

1524, principally by Gianpietro Caraffa, archbishop of Chieti in Naples, the Latin name of which is *Teate*, hence the name given to the order. Besides taking the usual monastic vows, they bound themselves to preach against heretics, to take upon them the cure of souls, to attend the sick and criminals, to abstain from possessing property, and not even to ask for alms, but to trust to Providence for support, expecting, however, that this support would be derived from the voluntary alms of the charitable. There were also Theatin nuns (called in French *Theatines*) who spent their whole time in solitude and prayer. The Theatins were principally established in Italy and France, in which latter country they subsisted till the revolution in 1789. In Italy the order is still numerous and influential.

**THE'ATRAL**, *† a.* Belonging to a theatre.

**THE'ATRE**, *n.* [Fr. *theatre*; L. *theatrum*; Gr. *θεατρον*, from *θεαμαι*, to see.]

1. Among the ancients, an edifice in which spectacles or shows and dramatic representations were exhibited for the amusement of spectators. Among the Greeks and Romans, theatres were the chief public edifices next to the temples, and in point of magnitude they surpassed the most spacious of the temples. The Greek and Roman theatres very closely resemble each other in their general form and principal parts. The building was of an oblong, semicircular form, resembling the half of an amphitheatre. The space appropriated to the seats of the spectators was termed *cavea* by the Romans, and *κολων* by the Greeks. The seats were all concentric with the orchestra, and were intersected in one direction by ascents or flights of steps, dividing the seats into so many compartments. The place for the players, in front of the seats, was called *scena* (*σκηνη*). The semicircular space between the *scena* and the seats of the spectators was called *orchestra* (*ορχηστρα*), appropriated by the Greeks to the chorus and musicians, and by the Romans to the senators. Besides these essential parts there were the *pulpitum* or stage, the *proscenium*, and *postscenium*, with regard to which parts the Greek and Roman theatres differed considerably.—2. In modern times, a house for the exhibition of dramatic performances, as tragedies, comedies, and farces; a playhouse; comprehending the stage, the pit, the boxes, galleries, and orchestra.—3. Among the *Italians*, an assemblage of buildings, which by a happy disposition and elevation, represents an agreeable scene to the eye.—4. A place rising by steps or gradations like the seats of a theatre.

Shade above shade, a woody theatre

In *bot.*, the term *theca* is used to indicate the reproductive organs of ferns, or those minute capsules, which are aggregated into little masses called *sori*. In the *Equisetaceæ* it expresses the assemblage of cases which are attached to scales arranged in a conical manner; in *Lycopodiaceæ*, it is used to indicate the kidney-shaped two-valved cases that contain the reproductive matter; and in mosses, it expresses the organs that enclose the sporules.—2. In *anat.*, *theca* is applied to the strong fibrous sheaths in which certain soft parts of the body are enclosed; as the canal of the vertebral column, and the canals in which many of the long tendons of the muscles of the hand and foot run.

**THE'CAPIHORE**, *n.* [Gr. *θηκα*, a case or cover, and *φορεω*, to bear or carry.] In *bot.*, the roundish stalk upon which the ovary of some plants is elevated; as in the caper bush. It is also called *podogynium* and *gynophore*.

**THECODA'C'TYLS**, *n.* [Gr. *θηκα*, and *δακτυλος*, a digit.] The name given by Cuvier to those geckos which have the toes widened throughout, and furnished beneath with transverse scales, divided by a deep longitudinal furrow, in which the claw may be entirely concealed.

**THE'CODONTS**, *n.* [Gr. *θηκα*, and *δους*, a tooth.] A tribe of extinct Saurian reptiles, distinguished by having the teeth implanted in sockets, either loosely, or confluent with the bony walls of the cavity. The thecodonts are the most ancient of all the aquatic or scaly Saurians. The name Thecodontosaurus has been given to one of the genera belonging to this tribe; its remains were found in the dolomitic conglomerate of Redland, near Bristol.

**THECOSTOMES**, *n.* [Gr. *θηκα*, and *στομα*, a mouth.] Latreille's name for those insects which have a suetorial mouth enveloped in a sheath.

**THEE**, *pron. obj. case of Thou*. [contracted from Sax. *thee*; Cimb. *thig*; Franche, *thee*; Goth. *thuk*. See **THOU**.]  
**THEE**, *† v. i.* [Goth. *thihan*; Sax. *thean*.] To thrive; to prosper.

**TIEFT**, *n.* [Sax. *thyfthe*. See **THIEF**.]

1. The act of stealing. In *jurisprudence*, the general name for the most ordinary class of offences against property, for which English law uses the term larceny. Simple larceny, or theft, is committed by wrongfully taking, against the will of the owner, and carrying away the goods of another, with the fraudulent and felonious intent wholly to deprive him of his property therein. Hence it requires an actual taking, and an actual carrying away for some distance, to constitute the

## THEISM

offences. Compound larceny, or theft, is when the theft is accompanied by aggravating circumstances; as, when it is committed upon the person, or consists in stealing from a dwelling house. Taking from the person in a violent manner is *robbery*, and stealing in a dwelling house after having broken therein is *burglary*. [See LARCENY.] In *Scots law*, theft is defined, "the intentional and clandestine taking away of the property of another, from its legitimate place of deposit, or other *locus tenendi*, with the knowledge that it is another's, and the belief that he would not consent to its abstraction; and with the intention of never restoring it to the owner." This distinction between the *infang thief*, or one taken while yet in sight, and the *outfang thief*, is now done away. But a distinction is still made between trifling theft or *pickery*, which is punishable with corporal punishment, imprisonment in bridewell, or fine, and theft properly so called. Simple theft is not punishable capitally unless of an aggravated character; as, theft under trust, when of a black description; the stealing of the larger animals, sheep included; theft to a great extent; theft by one habit and repute a thief; theft by breaking lockfast places, or by housebreaking.—2. The thing stolen; Exod. xxii.

**THEFT-BOTE**, *n.* [theft and Sax. *bote*, compensation.] In *law*, the receiving of a man's goods again from a thief; or a compensation for them, by way of composition, and to prevent the prosecution of the thief. This subjects a person to fine and imprisonment, as by this means the punishment of the criminal is prevented.

**THEIFORM**, *a.* Having the form of tea.  
**THE'INE**, *n.* [from *thea*, the generic name of the tea-plant.] A bitter crystallizable principle found in tea, and also in coffee, and some other plants. It forms fine white prisms of a silky lustre, which are soluble in water, alcohol, and ether, bitter, fusible, and volatile. It is considered to be the principle which gives to tea its refreshing and gently stimulating qualities, and is composed of 8 atoms carbon, 2 nitrogen, 5 hydrogen, and 2 oxygen. [See CAFFEINE.]

**THEIR**, *a. pronoun*. [Sax. *hiora*; Ice. *thairra*.] 1. *Their* has the sense of a pronominal adjective, denoting of them, or the possession of two or more; as, *their voices*; *their garments*; *their houses*; *their land*; *their country*.—2. *Theirs* is used as a substitute for the adjective and the noun to which it refers, and in this case it may be the nominative to a verb. "Our land is the most extensive, but *theirs* is the best cultivated." Here *theirs* stands as the representative of *their land*, and is the nominative to *is*.

Nothing but the name of zeal appears, 'Twixt our best actions and the worst of *theirs*. Denham.

In this use, *theirs* is not in the possessive case, for then there would be a double possessive.

**THE'ISM**, *n.* [from Gr. *theos*, God.] The belief or acknowledgment of the existence of a God, as opposed to *atheism*. *Theism* differs from *deism*, for although *deism* implies a belief in the existence of a God, yet it signifies in modern usage a denial of revelation, which *theism* does not.

II.

## THEN

**THE'IST**, *n.* One who believes in the existence of a God.

**THEISTIC**, *a.* Pertaining to **THEISTICAL**, *a.* theism, or to a theist; according to the doctrine of theist.

**THELPHU'SIANS**, *n.* The name given by Milne Edwards to a tribe of brachyurous crustaceans, forming the passage between the cancerians and the land crabs. All the known species live in the earth near the banks of rivers, or in humid forests, bearing a strong analogy to the land crabs.

**THEM**, *pron.* the objective case of *They*, and of both genders. [In our mother tongue, *them* is an adjective, answering to *the*, in the dative and ablative cases of both numbers. The common people continue to use it in the plural number as an adjective, for they say, bring *them* horses, or *them* horses are to be led to water.]

Go ye to *them* that sell, and buy for yourselves; Matth. xxv.

Then shall the king say to *them* on his right hand, Come, ye blessed of my Father; Matth. xxv.

**THEME**, *n.* [L. *thema*; Gr. *thema*, from *theto*, to set or place.] 1. A subject or topic on which a person writes or speaks; any thing proposed as a subject of discourse or discussion; a position or proposition. The preacher takes a text for the *theme* of his discourse.

When a soldier was the *theme*, my name Was not far off. Shak.

2. A short dissertation composed by a student on a given subject.—3. In *gram.*, a radical verb, or the verb in its primary absolute sense, not modified by inflections; as, the infinitive mode in English. But a large portion of the words called *themes* in Greek, are not the radical words, but are themselves derivative forms of the verb. The fact is the same in other languages.—4. In *music*, a series of notes selected as the text or subject of a new composition.

**THE'MIS**, *n.* [Gr.] In *Grecian myth.*, the goddess of law and order.

**THEMSELVES**, a compound of *them* and *selves*, and added to *they* by way of emphasis or pointed distinction. Thus we say, *they themselves* have done the mischief; they cannot blame others. In this case, *themselves* is in the nominative case, and may be considered as an emphatic pronoun. In some cases, *themselves* is used without *they*, and stands as the only nominative to the following verb. *Themselves* have done the mischief. This word is used also in the objective case after a verb or preposition. Things in *themselves* innocent, may under certain circumstances cease to be so.

They open to *themselves* at length the way. Milton.

**THEN**, *adv.* [Goth. *thane*; Sax. *thane*; G. *dann*; D. *dan*. See **THENCE**.] 1. At that time, referring to a time specified, either past or future.

**THEN'ARD'S BLUE**, *n.* Cobalt blue; a blue pigment prepared by digesting oxide of cobalt with nitric acid, and adding phosphate of soda, by which phosphate of cobalt is formed. This is mixed with gelatinous alumina, and the paste so formed is dried, and subjected to a cherry red heat, by which means the pigment is produced. [See COBALTE.]

**THENCE**, *adv.* (thens.) [Sax. *thanan*, *thanon*; G. *dannen*; from *than*, *dann*, then, *supra*. *Then* signifies properly place, or set time, from *setting*, and *thence* is derived from it. So the Germans say, *von dannen*, from *thence*.]

1. From that place.

When you depart *thence*, shake off the dust of your feet; Mark vi.

It is more usual, though not necessary, to use *from* before *thence*.

2. From that time.

There shall be no more *thence* an infant of days; Is. lxxv.

3. For that reason.

Not to sit idle with so great a gift Useless, and *thence* ridiculous about him. Milton.

**THENCEFORTH**, *adv.* (thens'forth.) [*thence* and *forth*.] From that time.

If the salt hath lost its savour, it is *thenceforth* good for nothing; Matth. v.

This is also preceded by *from*, though not from any necessity.

And from *thenceforth* Pilate sought to release him; John xii.

**THENCEFORWARD**, *adv.* [*thence* and *forward*.] From that time onward.

**THENCEFROM**, *adv.* [*thence* and *from*.] From that place.

**THEOBROMA**, *n.* A genus of plants, nat. order Sterculiaceae, the species of which yield the cacao, or *cocoa*, of commerce. They are trees with large simple leaves, and with the flowers in clusters, and are all of them natives of South America. The most important species is the *T. cacao*, the common cacao, or chocolate nut tree, which is indigenous in South America, but is extensively cultivated in the West Indies, and in the tropical parts of Asia and Africa. The capsules of the fruit are large, and contain each about 25 seeds; the pulp in which these are enveloped, has a sweet and not unpleasant taste, and is eaten by the natives. The cotyledons of the seeds contain a large quantity of oily albumen, which has an agreeable flavour, and on this account they are not only used as a principal article of diet by the natives of the countries in which they grow, but are now used for the

same purpose throughout the civilized world. The oil contained in the seeds is sometimes obtained separately, and called *cacao butter*. The seeds, reduced to a paste, and flavoured with honey, sugar, and certain other ingredients, constitute chocolate. [See CACAO.]

**THEOBROMINE**, *n.* A crystalline compound found in the seeds of *Theobroma cacao*. In composition it is analogous to theine or caffeine.

**THEOCRACY**, *n.* [Fr. *theocracie*; It. *teocrazia*; Sp. *teocracia*; Gr. *θεος*, God, and *κρατος*, power; *κρατος*, to hold.] Government of a state by the immediate direction of God; or the state thus governed. Of this species the Israelites furnish an illustrious example. The *theocracy* lasted till the time of Saul.

**THEOCRASY**, *n.* [Gr. *θεος*, God, and *κρασις*, mixture.] In ancient philosophy, the intimate union of the soul with God in contemplation, which was considered attainable by the newer Platonists.

**THEODICÆA**, } *n.* [Gr. *θεος*, and  
**THEODICY**, } *δικαιωσις*, just.] A vindication of the dealings of Divine Providence with man: the title of a work published by Leibnitz in 1710, in which the doctrine of Optimism is maintained.

**THEODOLITE**, *n.* [Qu. Gr. *θεοδωλις*, to view, and *δολος*, stratagem.] A most important surveying instrument for measuring horizontal angles, or the angular distances between objects projected on the plane of the horizon. This instrument is variously constructed, and provided with subordinate apparatus, according to the price, or the particular purposes to which it is to be applied. One of the most generally useful, consists of two concentric horizontal circular plates A and B, which turn freely on each other.

Theodolite.

The lower or graduated plate B, contains the divisions of the circle, and the

## THEOLOGIC

upper or vernier plate has two vernier divisions *a*, diametrically opposite, only one of which is shown in the cut. The vertical axis C, consists of two conical parts, the one working within the other. The external part is attached to the graduated plate B, and the internal to the vernier plate A. The plane of the circle is adjusted to the horizon by the screws *b, b, b*, acting against a plate of metal resting on the staff-head supporting the instrument. The vernier plate carries two spirit levels *c, c*, at right angles to each other, with their proper adjusting screws, by which the circle is brought accurately into the horizontal plane indicated by the levels. The horizontal axis of the vertical limb of the instrument is supported by a frame attached to the vernier plate, and turning along with it about the vertical axis. To the horizontal axis D, a telescope, with cross wires in its focus, is attached, which moves in the vertical plane, by the graduated circle E, and is used for observing the objects whose angular distance is to be measured, and also for taking altitudes, or measuring vertical angles, a spirit level is fixed beneath the telescope for its adjustment. F is a microscope for reading off the vernier divisions. The screws *g, h*, are for regulating and fixing the external part of the vertical axis C. To measure the angular distance between any two objects, the telescope is turned round along with the vernier circle, (the graduated circle remaining fixed,) until it is brought to bear exactly upon one of the objects; it is then turned round until it is brought to bear on the other object, and the arc which the vernier has described on the graduated circle, measures the angle required. The observation may be repeated any number of times in order to insure accuracy, by means of a repeating stand which turns round concentrically with the vertical axis of the theodolite. The theodolite is not only a most essential instrument in trigonometrical surveying for determining stations, and running base-lines, but also in geodetical operations, for assisting in determining the length of an arc of the meridian. For this latter purpose it requires to be constructed on a large scale.

**THEODOSIAN**, *a.* Belonging to the emperor Theodosius; relating to his code of laws.

**THEOLOGY**, *n.* [Fr. *theologie*; It. and Sp. *teologia*; Gr. *θεολογια*; *θεος*, God, and *λογος*, discourse.] Divinity; the science of God and divine things; or the science which teaches the existence, character, and attributes of God, his laws and government, the doctrines we are to believe, and the duties we are to practise. Theology consists of two branches, *natural* and *revealed*. *Natural theology* is the knowledge we have of God from his works, by the light of nature and reason. Such as his existence and unity; that he is possessed of certain perfections, the signatures of which are perceptible upon his works; that he governs the world; that it is our duty to honour and please him, by the practice of piety, justice, and benevolence; that the soul of man is immortal; and that there is a future state, in which the righteous will be rewarded, and the wicked punished. The doctrines and truths, however, which natural theology professes to teach, are, when taken by themselves, unsuitable to the present circumstances of mankind, and altogether inadequate for those purposes for which such knowledge is needed by man. Natural theology holds forth no certain hope of pardon to the guilty, and in the present enfeebled and corrupt state of our moral powers, the duties which it prescribes are absolutely impracticable. Hence, the grand foundation of theology is revelation, to which natural religion is a valuable, but not necessary, auxiliary. *Revealed theology*, or *supernatural theology*, as it is sometimes called, is that which is to be learned only from revelation, or that which is founded entirely upon the canonical books of the Old and New Testament. It is also sometimes called *positive theology*, as being founded upon the expressed will of God. Theology is variously divided, according to the method of treating the subject, and the part of the subject which is treated. — *Popular* or *Biblical theology*, that which is derived from the obvious meaning of the letter of Scripture, without any external aid, having for its fundamental principle that the Scriptures are to be interpreted by each individual reader, according to the ordinary laws by which the meaning of any other book is ascertained. This is the Protestant system, and stands opposed to the Roman Catholic system, or the *positive system* as it is called. — *Systematic theology*, that which reduces the scattered truths of revelation to the scientific form of a connected system; it also comprehends the investigation and discussion of those truths. — *Exegetical*

*theology*, that which consists in the knowledge of the documents which contain the revelation, the proof of their authority, and the explanation of their meaning.—*Historical theology*, that which exhibits a history of the workings and changes of religion among those who have professed it.—*Practical theology*, that which has for its subject the duties of practical religion, and the various modes of enforcing them. It comprehends *Homiletics*, *Catechetics*, *Liturgics*, and *Pastoral theology*.—*Dogmatic theology*, the science of exhibiting clearly, and of tracing to their results, the doctrines taught by revelation. It aims at forming a system which shall be accepted as binding by a large body of religionists; and then views all religious truth in the light of that system. The term is chiefly employed by German writers.—*Moral theology* teaches us the divine laws relating to our manners and actions, that is, our moral duties.—*Speculative theology* teaches or explains the doctrines of religion, as objects of faith.—*Scholastic theology* is that which proceeds by reasoning, or which derives the knowledge of several divine things from certain established principles of faith.

**THEOMACHIST**, *n.* [Gr. *Θεός*, God, and *μαχία*, combat.] One who fights against the gods.

**THEOMACHY**, *n.* [supra.] A fighting against the gods, as the battle of the giants with the gods.—2. Opposition to the divine will.

**THEOMANCY**, *n.* [Gr. *Θεός*, and *μαντία*, prophecy.] A species of prophecy in which a god himself was believed to reveal future events, as when any one consulted an oracle, among the heathen nations, the god himself was supposed to answer the inquirer.

**THEOPHILANTHROPIST**, *n.* [Gr. *Θεός*, God, and *φιλανθρωπος*, a lover of men.] One who practises or professes theophilanthropism.—2. In modern history, the title *theophilanthropists* was assumed by a society formed at Paris during the first French revolution. It had for its object to establish a new religion in place of Christianity, which had been abolished by the convention. The system of belief thus attempted to be established was pure deism, and, as was to be expected, proved a failure.

**THEOPNEUSTY**, *n.* [Gr. *Θεός*, God, and *πνεύμα*, breathing.] Divine inspiration.

**THEORBO** *n.* [It. *tiórba*; Fr. *tiórbe*

or *teorbe*.] A musical instrument made like a large lute, except that it has two necks or juga, the second and longer of which sustains the four last rows of chords which are to give the deepest sounds. The theorbo has eight base or thick strings, twice as long as those of the lute, which excess of length renders the sound exceedingly soft, and continues it a great length of time. It was also called the *archlute*, and was used chiefly, if not only, as an accompaniment to the voice. It has long fallen into disuse.

**THEOREM**, *n.* [Fr. *theoreme*; Sp. *añi* It. *teorema*; Gr. *θεωρημα*, from *θεωρεω*, to see.] In *math.*, a proposition to be proved by a chain of reasoning; any proposition which states its conclusion or makes any affirmation or negation; as distinguished from a *problem*, which requires a conclusion to be arrived at, without so much as stating whether that conclusion is even possible. A *theorem* wants demonstration only; a *problem* requires solution, or the discovery both of method and demonstration.—2. A speculative truth; a position laid down as an acknowledged truth.—3. In *alge.* or *analysis*, it is sometimes used to denote a rule, particularly when that rule is expressed by symbols or formulae; as, the binomial *theorem*, Taylor's *theorem*, &c.—A *universal theorem* extends to any quantity without restriction.—A *particular theorem* extends only to a particular quantity.—A *negative theorem* expresses the impossibility of any assertion.—A *local theorem* is that which relates to a surface.—A *solid theorem* is that which considers a space terminated by a solid, that is, by any of the three conic sections.

**THEOREMATICAL**, } to a theorem;  
**THEOREMIC**, } comprised in

**THEORIZER**, *n.* A theorist.

**THEORIZING**, *ppr.* Forming a theory.

**THEORY**, *n.* [Fr. *theorie*; It. *teoria*;

It. *teoria*; Gr. *θεωρία*, from *θεωρεω*, to see or contemplate.] 1. Speculation; a doctrine or scheme of things, which terminates in speculation or contemplation, without a view to practice. It is here taken in an unfavourable sense, as implying something visionary.—2. An exposition of the general or abstract principles of any science; as, the *theory* of music.—3. The science distinguished from the art; as, the *theory* and practice of medicine.—4. In the *arts*, the rules of an art as distinguished from the practice; or the knowledge of an art, so far as results from speculation on its nature, on the end which it proposes to attain, on the means which it is necessary to employ in order to attain the end proposed, &c., without being occupied with its practice.—5. A collected view of all that is known on any speculative subject; a connected body of truths having a dependence on one another, and belonging to one or more common principles; or it is a connected arrangement of facts, according to their bearing on some real or hypothetical law.—In *physical science*, a theory is defined, "An explanation of natural phenomena, founded on facts known to be true from evidence independent of those phenomena or appearances. Thus, we have the *theory* of gravitation, the *atomic theory*, *theories* of light, *theories* of heat, *theory* of combustion, *lunar theory*, *theory* of dew, *theories* of the earth, &c. A theory is often nothing else but a contrivance for comprehending a certain number of facts under one expression. Many theories are founded entirely on analogy, and such theories may have all degrees of evidence from the least to the greatest. The evidence of a theory increases with the number of facts which it explains, and the precision with which it explains them. It diminishes with the number of facts which it does not explain, and with the number of different suppositions that will afford explanations equally precise. A theory may not deserve to be rejected because it does not explain all the phenomena, if it explains a great number, and be not absolutely inconsistent with any one, but a single fact inconsistent with any theory may be sufficient to overturn it. *Theory* is distinguished from *hypothesis* thus: a theory is founded on inferences drawn from principles which have been established on independent evidence; a hypothesis is a proposition assumed to account for certain phenomena, and has no other evidence of its truth, than that it affords a satisfactory explanation of those phenomena. It is necessary to keep this distinction in view, as the terms *theory* and *hypothesis* are very frequently confounded both in speaking and writing. The terms *theory* and *practice* are also often used in a very loose and inaccurate manner, and are liable to a very common fallacy, namely, that of applying to one sense of a word, ideas or associations derived from another. By *practice*, as distinguished from *theory*, is often meant the application of that knowledge which comes from experience only, and is not sufficiently connected with any general principles to be entitled to the name of a theory; but as there is no theorist whose knowledge is all theory, so there is no practical man whose skill is all derived from experience. [See **Sig. 1.**]

## THERE

—*Theory of couples*, by couples in physics is meant a pair of equal and opposite forces not equilibrating each other, and the explanation or investigation of the phenomena or effects resulting from such forces is termed the *theory of couples*.—*Theory of equations*, that part of algebra which treats of the properties of rational and integral functions of a single variable, its great object being to develop the properties, and to evolve the values of the real and imaginary roots of equations of every degree.—*Theory of numbers*. Such notions have been held by Jacob Böhme, Swedenborg, and others.

**THERAPEUTÆ**, *n.* [Gr. *therapeia*, to worship.] A Jewish sect of devotees, of the first century after Christ; so called from the extraordinary purity of their religious worship. They withdrew into solitary places, where they devoted themselves to a life of religious contemplation.

**THERAPEUTIC**, *a.* [Gr. *therapeia*, from *therapeuo*, to nurse, serve, or cure.] Curative; that pertains to the healing art; that is concerned in discovering and applying remedies for diseases.

**THERMOMETER**, *n.* [Gr. *therm*, warm, from *therm*, heat, and *metron*, measure.] An instrument for measuring heat, or by which the temperatures of bodies are ascertained; founded on the property which heat possesses of expanding all bodies, the rate or quantity of expansion, being supposed proportional to the degree of heat applied, and hence indicating that degree. The thermometer consists of a slender glass tube, with a small bore, containing in general mercury or alcohol, which expanding or contracting by variations in the temperature of the atmosphere, or on the instrument being brought into contact with any other body, or immersed in a liquid or gas, which is to be examined, the state of the atmosphere, the body, liquid, or gas, with regard to heat, is indicated by a scale either applied to the tube, or engraved on its exterior surface. There are several kinds of thermometers, but the one in common use in this country is Fahrenheit's, so called from the name of the inventor. It consists of a small tube, terminating in a ball containing mercury, the air having been expelled, and the tube hermetically sealed. There are two points on the scale, corresponding to fixed and determinate temperatures; the first corresponds to the temperature of freezing water, and is marked 32°, the other corresponds to the temperature of boiling water, and is marked 212°; hence, the zero of the scale, or that point marked 0°, is 32° below the freezing point, and the interval or space between the freezing and boiling points consists of 180°. On the Continent, particularly in France, the centigrade thermometer is used. The space between the freezing and boiling points is divided into 100 equal parts or degrees, the zero being at freezing, and the boiling point at 100°. Reaumur's thermometer, which is in use in Germany, has the space between the freezing and boiling points divided into 80 equal parts, the zero being at freezing. The following formulae, deduced from the manner in which the three scales are divided, will serve to convert any given number of degrees of Fahrenheit's scale into the corresponding number of degrees on Reaumur's, and the centigrade scales, and vice versa: Let F, R, and C, represent any corresponding numbers of degrees on the three scales respectively, then:  $(F - 32) \times \frac{4}{9} = R$ , and  $(F - 32) \times \frac{5}{9} = C$ ;  $C \times \frac{9}{5} + 32 = F$ , and  $\frac{4}{5} \times C + 32 = F$ ; Also,  $\frac{4}{5} \times C = R$ , and  $\frac{4}{5} \times R = C$ . For extreme degrees of cold, thermometers filled with spirit of wine must be employed, as no degree of cold known is capable of freezing that liquid, whereas mercury freezes at about 39° below zero. On the other hand, spirit of wine is not adapted to high temperatures, as it is soon converted into vapour, whereas mercury

does not boil till its temperature is raised to 660°. Of all fluids, mercury is the best adapted for thermometers employed for indicating all ordinary temperatures.—*Register thermometer*. [See REGISTER.]—*Differential thermometer*. [See DIFFERENTIAL.] The thermometer indicates only the *sensible* heat of bodies, and gives us no information respecting the quantity of latent heat, or of combined heat, which those bodies may contain.

The same name was at first given to Leslie's differential thermometer.

**THERMOSCOPIC**, *a.* Pertaining to the thermoscope.

**THERMOSTAT**, *n.* [*therm*, and *statos*, standing.] An apparatus contrived by Dr. Ure, for regulating temperature in the processes of distillation and vaporization, in baths, hot houses, in adjusting the heat of stoves and furnaces, &c. It operates upon the principle that when two thin metallic bars of different degrees of expansibility are riveted or soldered face ways together, any change of temperature will cause the compound bar to bend, the side on which the least expansible bar is becoming concave, and the other convex. These flexures are made to operate in regulating valves, stop-cocks, stove registers, &c., and thereby to regulate the flow of heated liquids, or the admission or emission of air.

**THERMOSTATIC**, *a.* Pertaining to the thermostat.

**THERMOTENSION**, *n.* [Gr. *therm*, hot, and *tenso*, a stretching.] *Literally*, a stretching by heat. This word is applied by Professor Johnson to a process of increasing the direct cohesion of wrought iron. It consists in heating the metal to a determinate temperature, generally from 500° to 600°, of Fahrenheit, and in that state giving to it, by appropriate machinery, a mechanical strain or tension, in the direction in which the strain is afterwards to be exerted. The degree of tensile force applied is determined beforehand by trials on the same quality of metal at the ordinary temperature, in order to ascertain what force would, in that case, have been sufficient to break the piece which is to be submitted to thermotension.

**THIN**, *v. t.* [Sax. *thinnian*; Russ. *tonyu*; L. *tenuo*. See **ATTENUATE**.] 1. To make thin; to make rare or less thick; to attenuate; as, to *thin* the blood. — 2. To make less close, crowded, or numerous; as, to *thin* the ranks of an enemy; to *thin* the trees or shrubs of a thicket. — 3. To attenuate; to rarefy; to make less dense; as, to *thin* the air; to *thin* the vapours. — *Thin out*, in *geol.*: when strata gradually diminish in thickness until they disappear, they are said to *thin out*.

**THIN-CLAD**, *a.* Lightly dressed.

**THINE**, *pronominal adj.* [Goth. *theins*, *theina*; Sax. *thin*; G. *dein*; Fr. *tien*; probably contracted from *thigen*. See **THOU**.] Thy; belonging to thee; relating to thee; being the property of thee. It was formerly used for *thy*, before a vowel.

Then thou mightest eat grapes *thy* fill, at *thine* own pleasure; Deut. xxxii.

But in common usage, *thy* is now used before a vowel in all cases. The principal use of *thine* now is when a verb is interposed between this word and the noun to which it refers. I will not take any thing that is *thine*. *Thine* is the kingdom, and the power, and the glory. In the following passage *thine* is used as a substitute for *thy* righteousness.

I will make mention of *thy* righteousness, even of *thine* only; Ps. lxxi.

In some cases it is preceded by the sign of the possessive case, like nouns, and is then also to be considered as a substitute.

If any of *thine* be driven out to the utmost parts of heaven; Deut. xxx.

It is to be observed that *thine*, like *thou*, is used only in the solemn style. In familiar and common language, *your* and *yours* are always used in the singular number as well as the plural.

**THIN-FACED**, *a.* Having a meagre or attenuated visage.

**THING**, *n.* [Sax. *thing*, a thing, a cause; for his *thingon*, for his cause or sake; also, *thing* and *gethiny*, a meeting, council or convention; *thingan*, *thingian*, to hold a meeting, to plead, to supplicate; *thingere*, an intercessor; *thingung*, intercession; G. *ding*, a thing, a court; *dingen*, to go to law, to hire or haggle; *Dingstag*, Tuesday, [*thing's day*]; *beding*, condition, clause; *bedingen*, to agree, to bargain or contract, to cheapen; D. *ding*, thing, business; *dingen*, to plead, to attempt, to cheapen; *dingbank*, the bar; *dingdagen*, session-days; *dingen*, *dingster*, a pleader; *dingtaal*, plea; *Dingsdag*, Tuesday; *beding*, condition, agreement; *bedingen*, to condition; Sw. *ting*, thing, cause, also a court, assizes; *tinga*, to hire, bargain, or agree; Dan. *ting*, a thing, affair, business, case, a court of justice; *tinger*, to strike up a bargain, to haggle; *tingbog*, records of a court, [*thing-book*]; *tingdag*, the court day, the assizes; *tinghold*, jurisdiction; *tingmænd*, jurors, jury, [*thing-men*]; *tingsug*, a cause or suit at law, [*thing-sake*].] The primary sense of *thing* is that which comes, falls, or happens, like *event*, from L. *evenio*. The primary sense of the root, which is *tig* or *thy*, is to press, urge, drive, or strain, and hence its application to courts, or suits at law; a seeking of right. We observe that *Dingdag*, *Dingdag*, in some of the dialects

## THINK

signifies *Tuesday*, and this from the circumstance that that day of the week was, as it still is in some states, the day of opening courts; that is, *litigation day*, or *suitors' day*, a day of striving for justice; or perhaps *combat-day*, the day of trial by battle. This leads to the unfolding of another fact. Among our ancestors, *Tig* or *Tiig*, was the name of the deity of combat and war, the Teutonic Mars; that is, strife, combat deified. This word was contracted into *tive* or *tu*, and hence *Tiuesdag* or *Tues-dag*, Tuesday, the day consecrated to *Tiig*, the god of war. But it seems this is merely the day of commencing court and trial; *litigation day*. This *Tig*, the god of war, is *strife*, and this leads us to the root of *thing*, which is to drive, urge, strive. So *vez*, in Latin, is connected with *vez*, accused. For words of like signification, see **SAKE** and **CAUSE**.] 1. An event or action; that which happens or falls out, or that which is done, told, or proposed. This is the general signification of the word in the Scriptures; as, after these *things*, that is, events.

The principal duty chargeable in thirlage was *multure*, which consisted of a proportion varying from about  $\frac{1}{10}$  to about  $\frac{1}{3}$  of the grain carried, or of the meal or flour ground, deliverable to the miller or other possessor of the mill under the proprietor, or to the proprietor or superior himself. There were also small duties of *knaveship, bannock, lock and gowpen*, called *sequels*, [*see these terms*], which fell to the servants of the mill, according to the particular usage of each mill. This kind of servitude having become, in many cases, exceedingly oppressive, has fallen into disuse, an annual payment in grain or in money being substituted for it.

THIRST, n. (thurst.) [*Sax. thurst, thyrst*; G. *durst*; Dan. *tirst*, from *thir*, dry; *törst*, to dry, L. *torreo*, Sw. *torha*.]

1. A painful sensation of the throat or fauces, occasioned by the want of drink. Water is the proper object of this sensation or desire, although man, owing to disposition or his artificial mode of life, often satisfies it with other liquids. By satisfying thirst the body is provided with the quantity of water necessary for the repair of its tissues, and the maintenance of their proper moisture, and for the replacement of the fluid constantly lost by perspiration and other discharges. If

thirst be long unallayed it produces one of the most dreadful states which man can be compelled to endure. Thirst is a common symptom of febrile and other diseases.

Wherefore is it that thou hast brought us out of Egypt, to kill us and our children and our cattle with *thirst*? Exod. xvii.

Who did sin, *this* man or his parents, that he was born blind? John ix.

When they heard *this*, they were pricked to the heart; Acts ii.

In the latter passage, *this* is a substitute for what had preceded, viz., the discourse of Peter just delivered. In like manner, *this* often represents a word, a sentence, or clause, or a series of sentences or events. In some cases, it refers to what is future, or to be immediately related.

But know *this*, that if the good man of the house had known in what watch the thief would come, he would have watchd, and would not have suffered his house to be broken up; Matt. xxiv.

Here *this* refers to the whole subsequent member of the sentence. — 2. *By this*, is used elliptically for *by this time*; *as*, *by this* the mail has arrived. — 3. *This* is used with words denoting time past; *as*, I have taken no snuff for *this* month; and often with plural words. *This* way and *that* the wav'ring sails they bend. Pope.

A body of *this* or *that* denomination is produced. Boyle.

*This* and *that*, in this use, denote difference indefinitely. — 5. When *this* and *that* refer to different things before expressed, *this* refers to the thing last mentioned, and *that* to the thing first mentioned. [See *THESE*.]

Their judgment in *this* we may not, and in *that* we need not, follow. Hooker.

6. It is sometimes opposed to *other*.

Consider the arguments which the author had to write *this*, or to design the *other*, before you arraign him. Dryden.

[Sax. *thistel*; G. and D. *distel*; Sw. *tistel*.] The common name of prickly plants of the genus *Carduus*, a genus belonging to the class Syngenesia, and order Polygamia equalis, Linn.; nat. order Compositae. It consists of upwards of 30 species, most of which are inhabitants of Europe; *as* the musk thistle (*C. nutans*); milk thistle (*C. marianus*); welshed thistle (*C. acanthoides*); slender-flowered thistle (*C. tenuiflorus*). The name thistle is also given to numerous prickly plants belonging to other genera; *as* the spear-thistle (*Cnicus lanceolatus*); field thistle (*Cnicus arvensis*), a well-known plant, very troublesome to the farmer. The cotton thistle belongs to the genus *Onopordum*; the common cotton-thistle (*O. acanthium*) attains a height of from four to six feet. It is cultivated in Scotland as the Scotch thistle, but it is doubtful whether the thistle which constitutes the national badge has any existing type. The carline thistle belongs to the genus *Carlina*; the blessed thistle is the *Centaurea benedicta*; and the star-thistle is the *Centaurea calcitrapa*. The sow-thistle belongs to the genus *Sonchus*, and the globe-thistle to the genus

1001

*Echinops*. Some species of the thistle are admitted into gardens, where they form a pretty variety for borders. Thistles sow themselves extensively by means of their winged seeds, and hence they are great pests to the farmer. — *Order of the Thistle*, an ancient Scottish order of knighthood, sometimes called the order of St. Andrew. The date of its institution is not known, but it was revived by James V. of Scotland in 1540, again by James VII. of Scotland and II. of England in 1687, and a third time in 1703 by Queen Anne, who increased the number of knights to twelve, and placed the order on a permanent footing. In 1827, the number of knights was permanently extended to sixteen. The decorations of the order consist of a collar of enamelled gold, composed of sixteen thistles, interlaced with sprigs of rue, fastened to the mantle by a white riband; a small golden image of St. Andrew suspended from the collar; a gold medal having an image of St. Andrew within a circle, containing the motto of the order, "*Nemo me impune lacessit*" (no one provokes me with impunity); a thistle; a green riband to which the medal is attached, and a star which is worn on the left shoulder. The thistle, *as* is well known, is the national emblem of Scotland, and the national motto is the same as that of the order of the thistle.

We say, a man's *thoughts* are employed on government, on religion, on trade, or arts, or his *thoughts* are employed on his dress or his means of living. By this we mean that the mind is directed to that particular subject or object; that is, according to the literal import of the verb *think*, the mind, the intellectual part of man, is set upon such an object, it holds it in view or contemplation, or it extends to it, it stretches to it.

**THRASHING**, *ppr.* Beating out of the husk or off the ear, or separating from the straw; beating soundly with a stick or whip.

**THRASHING**, *n.* The operation by which grain is separated from the straw. This operation is performed in various ways; as, by the feet of animals, by a flail, or by a thrashing-machine. The first mode was that employed in the ages of antiquity, and it is still practised in the south of Europe, and in Persia and India. Oxen were generally employed for this purpose, either alone or with the addition of a kind of roller studded with iron knots, which the oxen dragged over the corn sheaves, which latter were spread on a circular floor in the form of a circle, the ends containing the grain being placed towards the centre. Thrashing by the flail is still practised in various parts of this and other countries, but thrashing machines have been very extensively introduced, which effect a great saving in time and labour to the farmer.—2. A sound drubbing.

**THRASHING-FLOOR**, *n.* [thrash and floor.] A floor or area on which grain is beaten out. In eastern countries, from the earliest ages, thrashing-floors were in the open air; but in colder and moister climates, such as ours, such floors must be under cover. Accordingly, a thrashing-floor with us is a space in a barn-floor, on which the grain is thrashed out by the flail.

**THRASHING-MACHINE**, *n.* A **THRASHING-MILL**, } chine  
for separating grain, as wheat, oats, barley, &c., from the straw; and in which the moving power is that of horses, oxen, wind, water, or steam. Water and horses are most generally employed. The thrashing-machine was invented in Scotland in 1758, by Michael Stirling, a farmer in Perthshire; it was afterwards improved by Mr. Andrew Meikle, a millwright in East Lothian, about the year 1785. Since that time it has undergone various other improvements. The thrashing-machines mostly employed at farm-houses may be briefly described as consisting of three rotative drums or cylinders, which receive motion from a water-wheel, or from a horizontal wheel driven by horses, or by steam power. The first drum which comes into operation has projecting ribs called beaters on its outer surface, parallel to its axis. This drum receives a very rapid motion on its

## THREAD

axis. The sheaves of corn are first spread out on a slanting table, and are then drawn in between two rollers called *feeding rollers*. The beaters of the drum act on the straw as it passes through the rollers, and beat out the grain. The thrashed corn is then carried forward to two successive drums or *shakers*, which, being armed with numerous spikes, lift up and shake the straw so as to free it entirely from the loose grain lodged in it. The grain is made to pass through a grated floor, and is generally conducted to a winnowing machine, which is driven by the same power which drives the thrashing-machine itself, by which means the grain is separated from the chaff. Thrashing-machines effect a great saving in labour; they do the work speedily, and at the time required; and they do the work better than the flail, separating the corn (particularly wheat) more completely from the straw.

In *English criminal law*, threats of personal violence, or any other threats by which a man of ordinary firmness may be put in fear, and by means of which money or other property is extorted from him, amount to the crime of robbery. It is also a misdemeanor at common law to threaten another in order to deter him from doing some lawful act, or to compel him to do some unlawful one, or to extort money or goods from him, or to obtain any other benefit to the person who makes the threat. In *Scots law*, threats, when used so as to infer just ground of fear, or even if less violent, when accompanied with importunity, will void a deed granted by any person while under the influence; and using threats of death to any person, or attempting or pretending to carry them into execution, in order to compel a confession of a real or supposed crime, is punishable at common law. [*See THREATENING.*]

**THREAT**, *v. t.* (threat.) To threaten, — *whicasee*. Threat is used only in poetry.

We know not the last radical, nor the primary sense of *three*. Owen, in his *Welsh Dictionary*, suggests that it signifies *fixed, firm*. But *see* **EXTRACT** and **TRICK**. It is probably contracted from *thrig*.] 1. Two and one.

This has been called the *golden rule*, on account of its great value. The immense variety of questions which may be solved by finding a fourth proportional defies all classification; but they may all be reduced to one form, viz., A produces B, what will C produce. [*See* **PROPORTION**, **RATIO**.]

times the whole alimentary canal, terminating in curd-like sloughs; occasionally occurring in successive crops. It is common in infants who are ill fed or brought up by hand. In adults, it commonly occurs in the advanced stages of many diseases, as typhoid and other acute fevers; in short, in nearly all cases in which there is great prostration of strength, thrush may occur.

3. The force exerted by rafters or beams against the walls which bear them is also termed a *thrust*.

*Note.*—Push and shove do not exactly express the sense of *thrust*. The two former imply the application of force by one body already in contact with the body to be impelled. *Thrust*, on the contrary, often implies the impulse or application of force by a moving body, a body in motion before it reaches the body to be impelled. This distinction does not extend to every case.

**THUGS**, *n.* (tugs.) [Hind. *thagna*; to deceive.] A secret and wide spread association of robbers and murderers in the upper provinces of Hindostan. The existence of this association was scarcely known to the British government before the year 1810, and no combined measures were taken to put it down until about 1830. The Thugs are considered to be a degenerate sect of Kall worshippers, and are peculiarly superstitious in their observances. To rob and murder is with them a sacred duty, and they are directed in all their proceedings by auguries, supposed to be vouchsafed by their tutelary goddess Behowanee. They usually move in gangs, consisting of from ten to two hundred or three hundred men, of all races, castes, sects, and religions, yet all joining in the worship of Kall, and sacrificing to their tutelary goddess every victim they can seize, and sharing the plunder among themselves. Still they shed no blood unless when forced by circumstances, but strangle their victims by means of a rope or handkerchief. Particular classes, however, are altogether exempt from their attacks; among whom are dancing girls, minstrels, sikhs, some religious mendicants, tailors, oilmen, blacksmiths and carpenters. In 1830 vigorous measures were adopted for their suppression, and between 1830 and 1837 upwards of 3000 were brought to justice. In consequence of these measures, the numbers of Thugs have rapidly diminished, and it is to be hoped that they will soon be totally extinct. The system practised by the Thugs is termed *Thugery*.

with something thick or blunt.—2. *a.* Heavy.—3. *Vulgarily*, stout; fat; large.

**THUN'DER**, *n.* [Sax. *thunder*, *thunor*; G. *donner*; D. *donder*; Sw. *dunder*; Dan. *dundren*; L. *tonitru*, from *tono*, to sound; Fr. *tonnerre*; It. *tuono*; Pers. *thondor* or *thundur*.] 1. The sound which follows an explosion of electricity or lightning; the report of a discharge of electrical fluid, that is, of its passage from one cloud to another, or from a cloud to the earth, or from the earth to a cloud.—Thunder is not lightning, but the effect of it. The character of the sound of thunder varies with the force and the distance of the explosion, the situation of the observer, the nature of the surrounding country, and it is no doubt affected also by the relative situations of the clouds. In general, it is considered

that lightning, by its heat, creates a partial vacuum in the atmosphere, and that the sudden rushing of air into the void space produces the sound; but this explanation will not account for the prolongation of the sound. The true cause seems to be the vibration of the air, agitated to a greater or less extent by the passage of the electric fluid with a greater or less degree of intensity. When lightning strikes an object near us in the earth, it produces a noise resembling that of a violent crash, which is not repeated or prolonged by reflection. When the explosion is more distant, a rumbling, irregular, and recurring noise is heard, which gradually dies away in the distance. Thunder frequently commences with a loud rattle, which may be occasioned by a series of discharges of electric matter in rapid succession, from a highly charged thunder cloud. The distance of a thunder cloud may be ascertained by counting the number of seconds which elapse between the time of seeing the flash, and that of hearing the report, and multiplying 1130 feet by that number of seconds, (1130 feet being the distance which sound travels per second); the result will be the distance of the cloud in feet. When the flash and the sound occur almost simultaneously, the thunder cloud is very near; but when 2 or 3 seconds elapse between the time of seeing the former and that of hearing the latter, the cloud may be considered at a safe distance. In thunder storms the lightning frequently does great mischief, destroying trees, killing men and animals, and even shattering buildings. During a thunder storm, persons should avoid going near any object or thing which acts as a conductor to the fluid; such as trees, hedges, water, fire places, gilt furniture, bell wires, and all large metallic surfaces. In a house, the safest place is in the middle of a room, and the security may be increased by sitting or lying upon a feather bed, a hair mattress, or thick woollen rug. Cellars are dangerous, as the discharge is often from the earth to a cloud, and buildings frequently sustain the greatest damage from lightning in the basement story. Thunder can scarcely ever be heard at the distance of more than 20 or 30 miles from the flash which produces it.

There were *thunders* and *lightnings*; Exod. xix.

2. Thunder is used for lightning, or for a thunderbolt, either originally through ignorance, or by way of metaphor, or

In popular lan., when lightning acts with extraordinary violence, and breaks or shatters any thing, it is called a *thunderbolt*, and ignorant people suppose it to be a hard body, otherwise it could not produce such effects.—2. Figuratively, a daring or irresistible hero; as, the Scipios, those *thunderbolts* of war.—3. Fulmination; ecclesiastical denunciation.

Extensive buildings, or those which have several pinnacles rising from their tops, require several rods for their protection, as it is found that the influence of a single rod is limited by the circumference of a circle described about the rod, with a radius equal to twice its height above the top of the building. Ships are protected from the effects of lightning by rods in the same manner as buildings. Thunder rods are also termed *conductors*, because they serve to conduct the electric fluid or lightning which strikes them safely and rapidly to the ground, and do not allow it to fall upon any part of the building.

THUN'DER-SHOWER, *n.* [*thunder* and *shower*.] A shower accompanied with thunder.

THUN'DER-STONE, *n.* Thunder stones are crystals of iron pyrites, of a cylindrical form, found in chalk beds, and were so named because they were fabulously supposed to be emitted by thunder. The same name is given to fossil echinites of the family cidaris.

THUN'DER-STORM, *n.* [*thunder* and *storm*.] A storm accompanied with lightning and thunder, generally preceded by a tempestuous wind, which soon subsides, and succeeded by violent showers of rain or hail, or both together. Such storms are common in tropical regions, and often cause great damage. In America, the violence of the wind at the commencement of the storm is sometimes equal to that of a hurricane, and then it is the explosions of electricity are the most terrible. This violence of the wind seldom continues longer than a few minutes, and after it subsides, the rain continues, but the peals of thunder are less frequent. These violent showers sometimes continue for hours; more generally, they are of shorter duration.

THUN'DER-STRIKE, *v. t.* [*thunder* and *strike*.] 1. To strike, blast, or injure by lightning. [*Little used in its literal sense*.]—2. To astonish or strike dumb, as with something terrible. [*Little used except in the participle*.]

The species are small undershrubs, most of them inhabitants of Europe; only one species is a native of Britain, viz., wild thyme, (*T. serpyllum*), although the Linnaean genus *Thymus* included other three British plants, but these are now referred to *Acinos* and *Calamintha*. The common or garden thyme, (*T. vulgaris*) has long been a favourite plant on account of its strong, pungent, aromatic odour and taste, and many varieties of it are cultivated in gardens. It is a native of the south-west parts of Europe, and is employed for culinary purposes. It yields an essential oil, which is extremely acrid and pungent. Wild thyme or mother of thyme, (*T. serpyllum*), grows in Britain on hills and in dry pastures, and has the same sensible properties as the garden thyme. Bees are said to be greatly attached to this plant, and it has been alleged to give a fine flavour to mutton. The volatile oil obtained from the wild and garden thyme, is frequently used as an application to carious teeth. It is also much used for culinary purposes.

and in New Holland. The *Daphnes* are valued for their fragrance; the various species of the Australian genus *Pimelea*, and the *Gnidias* and *Struthioles* of the Cape of Good Hope, are favourite objects of cultivation. The most remarkable property of the order is the causticity which resides in the bark. When applied to the skin it acts as a blister; and when chewed it produces pain in the mouth. The berries of *Daphne laureola*, are poisonous to all animals, except birds. The bark of some species is manufactured into cordage.

The *thyroid cartilage* constitutes the anterior, superior, and largest part of the larynx. The *thyroid gland* is situated on the sides and front of the lower part of the larynx, and the upper part of the trachea. It is copiously supplied with blood, but is not known to furnish any secretion. It is the seat of the bronchocœle or goitre.

In *bot.*, a species of inflorescence; a panicle contracted into an ovate form, or a dense or close panicle, more or less of an ovate figure, as in the lilac, privet, and horse chestnut.—2. A panicle, whose middle branches are longer than those of the base and apex.—3. In *Grecian and Roman antiquities*, one of the most common attributes of Bacchus and his followers. 1. An ornament or article of dress with which the ancient Persians covered their heads; a kind of turban. As different authors describe it, it must have been of different forms. 2. The alternate rising and falling of the waters of the ocean, and of bays, rivers, &c., connected therewith. The tide appears as a general wave of water, which gradually elevates itself to a certain height, then as gradually

## TIDE

sinks till its surface is about as much below the medium level as it was before above it. From that time the wave again begins to rise; and this reciprocating motion of the waters continues constantly, with certain variations in the height, and in the times of attaining the greatest degree of height and of depression. The alternate rising and falling of the tide wave are observed to take place, generally twice in the course of a lunar day, or of 24<sup>h</sup>. 48<sup>m</sup>. of mean solar time, in most of the shores of the ocean, and in the greater part of the bays, firths, and rivers which communicate freely with it. The tides form what are called a *flood* and an *ebb*, a *high* and *low* water. The whole interval between high and low water is called a *tide*; the water is said to *flow* and to *ebb*, and the rising is called the *flood tide*, and the falling the *ebb tide*. The rise or fall of the waters, in regard to elevation or depression, is exceedingly different at different places, and is also variable everywhere. The different heights of tide succeed each other in a regular series, diminishing from the greatest to the least, and then increasing from the least to the greatest. The greatest is called a *spring tide*, and the least a *neap tide*. This series is completed in about 15 days, or rather two series are completed in a lunar month. For the spring tide at any place happens at a certain interval of time, generally between one and two days, after new or full moon; and the neap tide, at a certain interval after the first or last quarter. Thus, the whole series of tides appears to be chiefly regulated by the moon, and to be only to a small extent under the influence of the sun. The moon, by her attraction, not only raises the waters of the ocean under her, but also at the same time raises them on the opposite side; the sun also raises similar waves by his attraction, but to a much less extent, owing to his great distance. Hence, the combined actions of the sun and moon, when these bodies are in conjunction, or opposition, that is at new or full moon, may be readily conceived to produce the spring tides, and the diminutions of each other's attractions when in quadratures to produce the neap tides. These tides will also vary, according as the sun or moon is in perigee or apogee, and likewise according to their respective declinations. The interval between two succeeding high waters is variable. It is shortest about new and full moon, being then about 12<sup>h</sup>. 19<sup>m</sup>.; and about the time of the moon's quadratures it is 12<sup>h</sup>. 30<sup>m</sup>. But these intervals are somewhat different at different places. The tides being of great importance to all commercial nations, it becomes an object of great importance to obtain the means of predicting them, but the subject, in a general point of view, is attended with many difficulties, and each place requires to have its own tide tables. The theory of the tides, considered as a consequence of the attractions of the sun and moon, unites some of the greatest difficulties that occur in the various departments of natural philosophy and astronomy.—*Atmospheric* tides, waves produced in the atmosphere similar to those produced in the waters of the ocean, and by the same causes, viz., the attractions of the sun and moon.—

## TIDE-TABLES

*Priming and lagging of the tides*, an effect of the combination of the solar and lunar tides. In the first and third quarters of the moon, the solar wave is to the westward of the lunar one, and consequently the observed tide, which is the result of the combination of the two waves, will be to the westward of the place it would occupy, if the moon acted alone, and the time of high water will be accelerated. Hence what is termed the *priming* of the tides. In the second and fourth quarters, the general effect of the sun is to produce, for a like reason, a retardation in the time of high water. Hence what is called the *lagging* of the tides. These effects are most remarkable about the time of new and full moon.—3. Stream; course; current; as, the *tide* of the times.

short hairs, and has no mane. The tiger is found in Asia only, and is rarely, if ever met with on this side of the Indus. He is the most formidable and cruel of all quadrupeds, and the scourge of the less inhabited parts of India. He is insidious, blood-thirsty, and malevolent, and seems to prefer preying on the human race. The bound with which the ambushed tiger throws himself upon his prey, is as wonderful in its extent, as it is terrible in its effects. Man is a mere puppet in his gripe; and the Indian buffalo is not only borne down by him, but carried off by his enormous strength. **Note**.—In this use, *till* is not a conjunction; it does not connect sentences like *and*, or *like or*. It neither denotes union nor separation, nor an alternative. It has always the same office, except that it precedes a single word or a single sentence; the time to which it refers being in one case expressed by a single word, as *now*, or *then*, or *time*, with *this*, or *that*, &c., and in the other by a verb with its adjuncts; as, occupy *till* I come, that is, *to* I come. In the latter use, *till* is a preposition

**TILL**, *v. i.* [Sax. *tilian*, *tiligan*, to work, to *toil*, to cultivate, to prepare; W. *telu*, to strain. In G. *bestellen*, from *stellen*, to set, to put in order, has the sense of *tilling*, cultivating. Those words are doubtless of one family.]

**TILT-HAMMER**, *n.* [*tilt* and *hammer*.] A heavy hammer used in iron works, which is worked by machinery, impelled either by a water-wheel or a steam-engine. Such hammers are extensively used in the manufacture of iron and steel. The hammer used for hammering the blooms of iron, is usually called a *lift* or *helve* hammer, and is sometimes of the enormous weight of six tons. The tilt-hammer, properly so called, is of lighter dimensions, and is worked with greater rapidity; a specimen of the kind usually employed in the manufacture of steel, and in the forging of anchors, axles, &c., is represented in the accompanying engraving.

Tilt-Hammer.

*a* is the shank or helve, usually formed of timber, and sometimes of wrought iron; it is hung upon an axis at about one-third of its length, and is worked by a series of revolving cams or tappets, *c, c*, fixed into the circumference of the *cam-ring*, *b*, mounted upon the shaft of a steam-engine or water-wheel. These cams act successively by depressing the shorter limb of the shank, *a*, until, by the continued revolution, it is disengaged, and the opposite extremity, armed with a heavy cast-iron hammer, *d*, descends with considerable force upon the anvil, *e*. Thus a repetition of blows is kept up as long as may be required.

**TILTING**, *ppr.* Inclining; causing to stoop or lean; using the game of thrusting with the lance on horseback; also, hammering with a tilt-hammer.

crest; *timmeren*, to build; *timmerhout*, timber; G. *simmer*, an apartment; *zimmer*, to square, fit, fabricate; *zimmerholz*, timber. If *m* is radical, which is probable, this word coincides with Gr. *dioma*, L. *domus*, a house, and Gr. *dioma*, the body. The primary sense is probably to set, lay, or found.] 1. That sort of wood which is squared, or capable of being squared, and fit for being employed in house or ship-building, or in carpentry, joinery, &c. We apply the word to standing trees which are suitable for the uses above mentioned, as a forest contains excellent timber; or to the beams, rafters, boards, planks, &c., hewed or sawed from such trees. But in the language of the customs, when a tree is sawn into thin pieces, not above 7 inches broad, it is called *batten*; when of greater breadth, such thin pieces are called *deal*. Timber is generally sold by the load. A load of rough or unhewn timber is 40 cubic feet, and a load of squared timber 50 cubic feet. In regard to planks, deals, &c., the load consists of so many square feet: thus, a load of 1 inch plank is 600 square feet. The most useful timbers of Europe are the oak, the ash, the Scotch pine, the larch, and the spruce fir; those of North America, are the hickory, the different species of pine, and some species of oak; those of tropical countries, are the teak tree, the different species of bamboo, and the palm. Wood is a general term, comprehending under it timber, dye woods, fancy woods, firewood, &c., but the word timber is often used in a loose sense for all kinds of felled and seasoned wood.—2. Hence the sense of *temples*, *L. tempora*, the falls of the head, also *tempest*, &c. See **TEMPEST**. Time is primarily equivalent to *season*; to the *Gr. αἰς* in its original sense, *opportunity*, *occasion*, a fall, an event, that which comes.] 1. 2. A proper time; a season.

3. Duration.

The equal and uniform flux of time does not affect our senses. Cyr.

Time is *absolute* or *relative*; *absolute* time is considered without any relation to bodies or their motions. It is conceived by us as unbounded, continuous, homogeneous, unchangeable in the order of its parts, and divisible without end. *Relative* time is the sensible measure of any portion of duration, by means of motion. Thus the diurnal revolution of the sun measures a space of time or duration. Hence,—4. A

## TIME

space or measured portion of duration. In this sense, time is measured by certain conventional or natural periods, and often marked by particular phenomena; as the revolution of the heavenly bodies, more especially the revolution of the sun, or the rotation of the earth on its axis. Time is divided into years, months, weeks, days, hours, minutes, and seconds, but of these portions the years and days only are marked by celestial phenomena. In order to measure time we employ some equable motion, and we judge those times to be equal, which pass while a moving body proceeding with a uniform motion passes over equal spaces. The machines employed for measuring time are clocks, watches, chronometers, clepsydras, hour-glasses, and dials, but the three former are those chiefly used.—6. Life or duration in reference to occupation. One man spends his time in idleness; another devotes all his time to useful purposes.

Repetition; doubling; addition of a number to itself; as, to double cloth four times; four times four amount to sixteen.—10. In music, the relative duration of sounds or the measurement of that duration. The term is also used to signify that which divides a bar into two or three equal parts, and subdivides these; and likewise the movement, that is, the quickness or slowness of a composition. The duration of a single sound is known by the particular note, that is, as minim or crotchet, &c. The semibreve is considered as the measure note, it being the longest. Its average length is about four beats of a healthy man's pulse. In regard to the division of bars, the time is either duple or triple, of which there are several varieties. A variety of terms are employed to indicate the movement, as *andante*, *adagio*, *allegro*, &c. In concerts, it is all important that the performers keep time, or exact time.—11. The state of things at a particular period; as when we say, good times, or bad times, hard times, dull times for trade, &c. In this sense, the plural is generally used.—12. The present life; as, in time or eternity.—13. In gram., tense.—14. Among phrenologists, one of the perceptive faculties. Its organ is situated on each side of eventuality. This faculty gives the power of judging of time, and of intervals in general. It is essential to music and versification.—In time, in good season; sufficiently early. He arrived in time to see the exhibition.—2. A considerable space of duration; process or continuation of duration. You must wait patiently; you will in time recover your health and strength.—At times, at distinct intervals of duration. At times he reads; at other times he rides.

It melts at 442°, and if heated to whiteness in air, it takes fire and burns with a white flame, forming peroxide of tin.

Tin is rather a scarce metal, being found in few places of the world in any quantity. The mines in Cornwall are its most productive source; it also occurs in Bohemia, Saxony, and Spain; in Malacca and Banca, in Asia; in Mexico and Chili; and in Massachusetts, in North America. There are only two ores of tin: the native peroxide, called *tin stone*, and the double sulphuret of tin and copper, called *tin pyrites*,—which see. The peroxide of tin is found in Cornwall in two forms: 1. In veins where it is blended with several other metals; as arsenic, copper, zinc, and tungsten; 2. In loose rounded masses, grains, or sand in alluvial soil, in which state it is called *stream tin*. The former, when reduced to the metallic state, yields *black tin*, while the latter yields *grain tin*, which is the purer of the two. What is termed *wood tin* is found in reniform and botryoidal masses, or in wedge-shaped pieces. Oxygen combines with tin, forming the *protoxide*, *sesquioxide*, and *peroxide* of tin. Chlorine unites with tin, forming the *protocliloride* and *perchliloride* of tin. The compounds of sulphur and tin are the *protosulphuret*, *sesquisulphuret*, and *perarsulphuret*. The uses of tin are numerous. It is much used as a covering to several other metals, as in tin-plate, and cooking vessels of copper. Combined with copper it forms *bronze*, *bell-metal*, and several other useful alloys. With lead it forms *pewter*, and solder of various kinds. Tin-foil coated with mercury forms the reflecting surface of glass-mirrors. The solutions of tin in the nitric, muriatic, nitro-sulphuric, and tartaric acids, are much used in dyeing. Tin is much

tive.

A robe of *tissue*, stiff with golden wire.

*Dryden.*

2. In *anat.*, texture or organization of parts. The peculiar intimate structure of a part is called its *tissue*. A part of a fibrous structure is called a *fibrous tissue*. The organs of the body are made up of simpler elements, some generally diffused through the body, and others peculiar to particular organs. These simpler structures are called the *tissues* of the body; as, the cellular *tissue*; the mucous *tissue*, &c. The cellular *tissue* is the cellular membrane.

—3. In *bot.*, the minute elementary parts of which the organs of plants are composed. These elementary structures differ from each other, and are so minute as generally to be distinctly visible only with the aid of the microscope. They are named *elementary organs*, *organic tissue*, or *vegetable tissue*. When a leaf or a portion of the stem of one of the higher plants is submitted to the microscope, it is found to consist, 1. of a thin transparent homogeneous membrane, which is arranged in the form of cells or cylindrical tubes; 2. of fibres which are arranged in a spiral form in the interior of the cells or tubes; and, 3. of a fluid, filling the cells, and existing between them, and containing in it globules of various sizes and kinds. These parts constitute what are known respectively as *elementary membrane*, *elementary fibre*, and *organic mucus*. The elementary fibre is only found in the higher forms of plants, the other two are found in all plants. The *tissues* of plants then are composed of elementary membrane and elementary fibre, and the principal forms under which they exhibit themselves constitute the *fibrous tissue*, *cellular tissue*, and *vascular tissue*. *Fibrous tissue* is that in which elementary fibre alone is apparent. *Cellular tissue* is composed of membrane in the form of cells or cavities which are closed on all sides, and are commonly of a spheroidal form, although they often assume various other forms. The pith of plants is entirely composed of cellular tissue, but it enters largely into the structure of other parts, and in many is the only tissue. When the cells are composed of membrane and fibre combined, or of fibre alone, they constitute the *fibro-cellular tissue*. *Vascular or tubular tissue* is composed of very elongated membranous tubes, tapering at each end. It comprehends the *woody* and *laticiferous tissues*. When the tubes have within them a spiral fibre, or their walls marked with broken spiral lines or dots, arranged in a circular or spiral direction, they constitute *fibro-vascular tissue*.—4. **TITANIUM**, *n.* In *mineral.*, a metal discovered by Gregor in 1791, in a black sand in Cornwall. It was afterwards discovered by Klaproth in some other minerals, and he gave it the name it now bears. In 1822, Wollaston examined it, and ascertained its properties. It is found oxidized in several minerals; and occurs occasionally in the metallic form, in the slag iron works; as small enclitic crystals, exactly similar to bright copper in appearance; of specific gravity 5.3, and very infusible. When heated with nitro they are oxidized, producing titanic acid. Titanium is dissolved in a mixture of nitric and hydrofluoric acid, under a very high temperature. Oxygen and titanium combine, forming the protoxide, which is a deep purple-coloured powder, and the peroxide or titanic acid. Titanium also combines with chlorine forming a bichloride, and with sulphur forming a bisulphuret. The ores of this metal are called *menachanite*, from Menachan in Cornwall, where it was originally found; *iserine*, from the river Iser, in Silesia; *nigrine*, from its black colour; *sphene*, *rutile*, *brookite*, *axotomous iron*, *erich-tonite*, *ilmenite*, *mohsite*, *eschynite*, *greenovite*, and *octahedrite* or *anatase*.

## TITILLATION

*sonal*, when accruing from labour, art, trade, and navigation; *predial*, when issuing from the earth, as, hay, wood, grain, and fruit; and *mixed*, when accruing from beasts, which are fed from the ground. Another division of tithes is into *great* and *small*. *Great tithes*, consist of all species of corn and grain, hay, and wood; and *small tithes*, of predial tithes of other kinds, together with mixed and personal tithes.

The great tithes belong to the rector, and are hence called *parsonage* tithes; and the latter are due to the vicar, and are hence called *vicarage* tithes. Tithes are either due *de jure* or by custom; to the latter class belong all personal tithes. But possession is not essential to a complete title. A title to personal property may be acquired by occupancy. A claim is not a title. Title, in the legal sense, signifies the means by which a man becomes seized of real property, or possessed of personal property; as, title by descent, title by purchase, title by administration, title by bankruptcy, title by marriage, &c. The term is also used to signify, generally, a right to land. The legislature assembles annually to make and amend laws. The court will sit in February to try some important causes.—23. It precedes the radical verb after adjectives, noting the object; as, ready to go; prompt to obey; quick to hear, but slow to censure.—24. It precedes the radical verb, noting the object.

In the last, it is equivalent to *in* or *on*; *in* or *on* the morrow. The words may be considered as compounds, *to-day*, *to-night*, *to-morrow*, and usually as adverbs. But sometimes they are used as nouns; as, *to-day* is ours.—*To* and *fro*, backward and forward. In this phrase, *to* is adverbial.—*To the face*, in presence of; not in the absence of.

I withstood him face to face; Gal. ii.

*To-morrow*, *to-morrow*, and *to-morrow*; Creeps in this petty pace from day to day.

*Shak.*

**Note.** In the foregoing explanation of *to*, it is to be considered that the definition given is not always the sense of *to* by itself, but the sense rather of the word preceding it, or connected with it, or of *to* in connection with other words. In general, *to* is used in the sense of moving toward a place, or toward an object, or it expresses direction toward a place, end, object, or purpose. *To* is often used adverbially to modify the sense of verbs; as, *do come to*; *to leave to*. The sense of such phrases is explained under the verbs respectively. In popular phrases like the following, "I will not come; you shall *to*, or *too*," a genuine Saxon

phrase, *to* denotes moreover, besides, *L. insuper.*

**TOAD**, *n.* [*Sax. tade, tadige.*] A paddock; the common name of the batrachian reptiles of the genus *Bufo*. Toads have a thick bulky body covered with warts or papillæ; a thick lump behind the ears, pierced with pores from which issues a milky and fetid fluid. They are hideous and disgusting animals, whose bite, saliva, &c., were formerly considered poisonous, but are now ascertained to be harmless. They have been known to remain whole years in walls, hollow trees, in the earth, and even, it is said, in the heart of a stone. Toads are found in all quarters of the world. Charlevoix, in his History of St. Dominique, says that the instrument used in smoking was called *tabaco*.] A plant, a native of America, of the genus *Nicotiana*, the *N. tabacum*, the dried leaves

of which are much used for smoking and chewing, and in snuff. As a medicine, it is narcotic, emetic, and cathartic; and it possesses two additional powers at least, if not more. Tobacco has a strong disagreeable smell, and an acrid taste. When first used it sometimes occasions vomiting, &c., but the practice of using it in any form soon conquers distaste, and forms a relish for it that is strong and almost unconquerable. There are many other species of *Nicotiana*, most of which yield tobacco for smoking, and many of these are cultivated in the gardens of Europe. Tobacco is now very extensively cultivated on the European continent, in the Levant, and in India, but the tobacco of the United States is still very generally admitted to be superior to most others. The tobacco plants belong to the nat. order Solanaceæ. [See **NICOTIANA**.]

**TOLERATION**, *n.* [L. *toleratio*.] The act of tolerating; the allowance of that which is not wholly approved; appropriately, the allowance of religious opinions and modes of worship. In a state, when contrary to or different from those of the established church or belief. *Toleration* implies a right in the sovereign to control men in their opinions and worship, or it implies the actual exercise of power in such control. Every person is as much entitled to liberty of opinion on religious subjects as on any other, and has a right to adopt any mode of worship, and hold any doctrines which are not inconsistent with the peace and safety of the state, and the moral welfare of its members. The civil magistrate has a right to check the propagation of opinions and doctrines, which tend only to sap the foundations of morality, and to disturb the peace of society; but he has no right to restrain men from publicly professing any system of faith, which comprehends the being and providence of God, the great laws of morality, and a future state of rewards and punishments. There are two kinds of toleration, as laid down by Paley: 1. The allowing to dissenters the unmolested profession and exercise of their religion, but with an exclusion from offices of trust and emolument in the state; this is called a *partial* toleration. 2. The admitting dissenters, without distinction, to all the civil privileges and capacities of other citizens; this is called a *complete* toleration. Where no power exists or none is assumed to establish a creed and a mode of worship, there can be no *toleration*, in the strict sense of the word, for one religious denomination has as good a right as another to the free enjoyment of its creed and worship.—2. In an *eccles. sense*, the allowance which the church grants to its members to differ in certain opinions, not considered fundamental.—*Toleration act*, an act passed in the reign of William and Mary, in favour of dissenters and Roman catholics.

The tone of an instrument, is its peculiar sound with regard to softness, richness, fulness, evenness, and the like.—8. In med., that state of a body, in which the animal functions are healthy and performed with due vigour. *Tone*, in its primary signification, is *tension*, and tension is the primary signification of strength. Hence its application to the natural healthy state of animal organs. *Tone*, therefore, in medicine, is the strength and activity of the organs, from which proceed healthy functions: so we say, the body is in a *sound* state, the health is *sound* or *firm*.—9. In painting, the harmonious relation of the colours of a picture in light and shade. The term is often used to qualify, or as synonymous with, *depth*, *richness*, and *splendour*, in pictures. **TONNAGE**, *n.* [from *ton*.] The weight of goods carried in a boat or ship.—2. The cubical content or burthen of a ship in tons; or the amount of weight which she may carry. Properly speaking, the tonnage of a ship is an expression for the interior capacity by the number of tons of sea water which it could contain; hence, if the interior capacity were found in cubic feet, and this divided by 35 (the number of cubic feet of sea-water which are equal in weight to one ton), the quotient would be the tonnage. The tonnage, however, is frequently understood to express the capacity, by the

## TONSOR

number of tons of sea-water which might be contained between a horizontal plane passing through the ship when she floats in still water, with only her equipments and stores on board, and a horizontal plane passing through the ship when laden; that is, between what are called the *light-water* and *load-water* planes; the contents of that part of the ship expressed in cubic feet being divided by 35, as in the former case. The result evidently gives the weight of the ship's cargo merely. As, however, the determination of the tonnage of ships, according to either of the above cases, is very laborious and difficult in practice, several empirical rules have been laid down, by which an approximate value of the tonnage may be more easily found. Tonnage is the only term used to give an idea of the size of merchant ships, which are invariably spoken of according to their tonnage, or as being ships of 100, 500, or 1000 tons. Not only are all dues and customs levied according to the tonnage, but ships are also built, and bought and sold for a certain price per ton of their admeasurement. Sometimes the tonnage of goods and stores is taken by weight and not by measurement.—3. A duty or impost on ships, formerly estimated at so much per ton of freight, but now proportioned to the registered size of the vessels.—*Tonnage and Poundage*. [See **POUNDRAGE**.]

Hence, *tonsure* is used to denote entrance or admission into holy orders.—3. and in this sense may be looked upon as signifying, in reference to the localities above named, what typhoon or tyfoong means in the seas of China and the eastern Archipelago. Tornados are usually accompanied with severe thunder, lightning, and torrents of rain;

the pectorals. There are several species, which are commonly confounded with each other. These fishes are usually taken in forty fathoms water, on the coasts of France and England, and in the Mediterranean. A touch of them occasions a numbness in the limb, accompanied with an indescribable and painful sensation, and is really an electric shock. The electrical apparatus in the Torpedo, consists of small membranous tubes, which occupy the space

between the head, the pectoral fins, and the branchiae. They are disposed like a honey comb, and divided by horizontal partitions into small cells, which are filled with a mucous substance, the whole being in many respects analogous to the galvanic pile. The shocks given by the Torpedo are very severe, and are supposed to be used by the animal, both as a means of defence and of disabling its prey. When dead, they lose the power of producing this sensation.—2. A machine invented by Robert Fulton, an American, for destroying ships, by blowing them up. The principal part of the apparatus consisted of a copper box or case, enclosing a certain quantity of gunpowder and combustible matter. These cases were to be applied under the keels of the vessels to be destroyed by means of a kind of submarine boat. The inventor, who was encouraged in his scheme by Bonaparte, attempted, by means of his *infernal machine*, to blow up a British man-of-war in 1801, but providentially failed, owing to the vessel suddenly changing her position. **TORPENT**, *a.* [*L. torpens, torpeo*] Benumbed; torpid; having no motion; or activity; incapable of motion.

**TORRENT**, *a.* Rolling or rushing in a rapid stream; as, waves of *torrent* fire.

**TORRICELLIAN**, *a.* Pertaining to Torricelli, an Italian philosopher and mathematician, who, in 1643, discovered the true principle on which the barometer is constructed, by means of an experiment called from him the *Torricellian experiment*. This experiment consisted in filling with mercury a glass tube closed at one end, and then inverting it, and bringing the open end under the surface of mercury in a vessel; when the column of mercury in the tube was observed to descend, till it stood at a height equal to about 29½ inches above the level of the mercury in the vessel, leaving what is considered to be a perfect vacuum at the top, between the upper extremity of the column and that of the tube. This experiment led to the discovery that the column of mercury in the tube is supported by the pressure of the atmosphere, acting on the surface of the mercury in the vessel, and that this column is an exact counterbalance to the atmospheric pressure. [*See BAROMETER*.]—*Torricellian tube* is a glass tube thirty or more inches in length, open at one end, and hermetically sealed at the other, such as is used in the barometer.—*Torricellian vacuum*, a vacuum produced by filling a barometer tube with mercury, as in the Torricellian experiment; the vacuum above the mercurial column in the barometer.

**TORRID**, *a.* [*L. torridus*, from *torreo*, to roast.] 1. Parched; dried with heat; as, a *torrid* plain or desert.—2. **TORRIDNESS**, *n.* The state of being very hot or parched.

**TORSE**, *n.* [*Fr. torse*; *L. tortus*.] In *her.*, a wreath.

**TORSEL**, *n.* [*supra*.] Any thing in a twisted form.—2. In *arch.*, torsels are the pieces of timber lying under the mantle-tree. They are otherwise called *tassels*.

**TORSION**, *n.* [*L. torsio*, from *torqueo*, to twist.] The act of turning or twisting.—2. In *mech.*, the twisting or wrenching of a body by the exertion of a lateral force. The resistance which cylinders and prisms formed of different substances oppose to torsion, furnishes one of the usual methods of determining the strength of materials. Such machines as capstans and windlasses, also axles which revolve with their wheels, are, when in action, subject to be twisted, or undergo the strain of torsion. If a slender rod of metal be suspended vertically, so as to be fixed at the point of suspension, and then twisted through a certain angle, it will, when the twisting force

## TORSION

ceases to act, untwist itself, or return in the opposite direction with a greater or less force or velocity until it come to rest in its original position. The limits of torsion within which the body will return to its original state, depend upon its elasticity; and the force with which it tends to recover its natural state is called *elasticity of torsion*. This force is always proportional to the angle through which the body has been twisted. If a body is twisted so as to exceed the limit of its elasticity, its particles will either be wrenched asunder, or it will take a *set*, and will not return to its original position on the withdrawal of the twisting force. The word *torsion* is also used to signify that force with which a thread or slender wire returns to a state of rest when it has been twisted by being turned round on its axis; the thread or wire, which is suspended vertically, being attached at the upper extremity to some fixed object, and having at its lower extremity a weight with a horizontal index, or a stirrup, which is to carry a needle or bar in a horizontal position.—*Torsion balance*, or *Balance of torsion*. If a piece of very fine wire, silk, or spun glass, be suspended in the manner above stated, and then twisted, it will, when released, begin to untwist itself, and by the momentum acquired in the act of untwisting, will twist in the opposite direction to a greater or less extent, according to the amount of twisting to which it had been subjected. It will then begin to return; and thus by a series of oscillations continually diminishing in extent, it will at length gradually settle in its original position. Now, if a needle or an index be attached to the lower extremity of the suspended wire or thread, and a graduated circle placed immediately beneath the index in a horizontal position, so that the centre of the circle may be directly below the point of suspension of the index, the apparatus thus constructed will form the *torsion balance*. This balance has been employed to measure certain forces too minute to be estimated by the ordinary methods, and by means of it Coulomb was enabled to determine, by direct experiment, the laws which govern the variation of magnetic and electric forces. By means of the same instrument, Cavendish afterward detected and measured the attraction of gravitation existing between balls of lead. To measure small forces, such as those of electricity, magnetism, &c., with the torsion balance, they are made to act upon one extremity of the index, and thus cause it to turn round, and when the force is in equilibrio with the tendency of the suspended wire to untwist, the angle which the index makes with its original position, which is called the *angle of torsion*, and which is measured by the graduated circle, is the measure of the force employed. In making experiments with the torsion balance, the length of the suspended wire, its diameter, and the weights attached to its lower extremity, must be taken into account. When the balance is adapted to measure electric forces, it is called the *torsion electrometer*; when it is adapted to measure galvanic forces, it is called the *torsion galvanometer*; and, when applied to measure magnetic forces, it

TORTOISE, n. (tor'tis.) [from *L. tortus*, twisted.] 1. An animal of the order Testudinata, or Chelonians, covered with a shell or crust. The tortoises form a numerous and highly interesting order (Testudinata) of reptiles. They are also called Chelonians from *χελών* (*Chelone*), the Greek name for a tortoise, and are readily distinguished by the double shield in which their body is enclosed, whether they are terrestrial, fresh water, or marine. They were all comprised by Linn. under his genus *Testudo*, but modern naturalists

have subdivided them chiefly according to the forms and teguments of their shell, and their feet. According to some of the modern arrangements, the land tortoises form the genus *Testudo*;

the fresh-water tortoises, the genus *Emys*; and the sea tortoises, the genus *Chelonia*. Those *Chelonians* which resemble fresh-water tortoises, but are distinguished from them by their mouth, which opens cross-wise, and is unarmed with the horny beak common to the former, form the genus *Chelys*, while the soft shelled tortoises form the genus *Trionyx*.—2. horny scales or plates which form the covering of this animal, under the name of *tortoise-shell*, are extensively used in the manufacture of combs, snuff-boxes, &c., and in inlaying and other ornamental work. The goodness of tortoise-shell depends mainly on the thickness and size of the scales, and in a smaller degree upon the clearness and brilliancy of the colours. The best tortoise-shell is that of the Indian archipelago.

Torture may be and is inflicted in a variety of ways, as by water or by fire, or by the boot or thumbkin. But the most usual mode is by the rack or wheel. Torture was virtually abolished in England in 1640, and in Scotland in the 7th year of Queen Anne.

**TORY**, *n.* [said to be an Irish word, and meaning originally a robber; the Irish robbers of former days, when they called to a party to stand and deliver, usually crying, *Tora, tora!* Give, give!] The name given to an adherent to the ancient constitution of England and to the apostolical hierarchy. One who, in political principles, always leans to church and state; who supports the regal, ecclesiastical, and aristocratical institutions of the country, and who is jealous of the extension of democratic power. The *tories* thus differ from the *whigs* and *radicals*, who, on the other hand, are jealous of the encroachments of the crown, and the privileged classes, and who give their support, in various degrees, to an extension of the power of the people. Of late years the term *conservative* has been adopted by the *tories*, as tending to convey the best idea of their principles. [See *CONSERVATIVE*.] The distinctions of *tory* and *whig*, as applied to political partisans, were not known before the year 1678, in the reign of Charles II. [See *WHIG*.]

Perhaps the most remarkable species is the *T. melanoleucus*, a native of North America, known to sportsmen by the name of Tell-tale. Although the sense of touch is diffused over the whole body, it is much more exquisite in some parts than others. In man the hand is the principal organ of touch, and the greatest degree of sensibility resides in the extremities of the fingers. By the sense of touch we are enabled to ascertain the properties of bodies, in so far as they can be ascertained by contact. Tournaments were usually held on the invitation of some prince, which was proclaimed by heralds throughout his own dominions, and likewise at foreign courts, so that parties from different countries might join in such exercises. ## TRADE

from *L. tracto*, to handle, use, *treat*. The *Fr. traite, traitier*, are the same words.] 1. The act or business of exchanging commodities by barter; or the business of buying and selling for money; commerce; traffic; barter. Trade comprehends every species of exchange or dealing, either in the produce of land, in manufactures, in bills or money. It is, however, chiefly used to denote the barter or purchase and sale of goods, wares, and merchandise, either by wholesale or retail. Trade is either *foreign*, or *domestic* or *inland*. *Foreign* trade consists in the exportation and importation of goods, or the exchange of the commodities of different countries. *Domestic* or *home* trade is the exchange or buying and selling of goods within a country. Trade is also by the wholesale, that is, by the package or in large quantities, or it is by retail, or in small parcels. The *carrying* trade is that of transporting commodities from one country to another by water. Trade was originally carried on chiefly by barter; but it is now carried on chiefly by means of money or bills.—2. The business which a person has learned and which he carries on for procuring subsistence or for profit; occupation; particularly, mechanical employment; distinguished from the liberal arts and learned professions, and from agriculture. **TRADE-WINDS, n.** [*trade* and *wind*.] The trade-winds are those perpetual or constant winds which occur in all open seas, on both sides of the equator, and to the distance of about 30 degrees north and south of it. They are so named because they are favourable to navigation and trade. On the north of the equator, their direction is from the north-east, (varying at times a point or two of the compass either way); on the south of the equator they proceed from the south-east. The origin of the trade-winds is this:—the great heat of the torrid zone rarefies and makes lighter the air of that region, and in consequence of this rarefaction, the air rises, and ascends into the higher regions of the atmosphere. To supply its place, colder air from the northern and southern regions rushes towards the equator, which, also becoming rarefied, ascends in its turn. The heated

## TRADITIONAL

air which thus ascends into the upper regions of the atmosphere, being there condensed, flows northward and southward to supply the deficiency caused by the under currents blowing towards the equator. These under currents coming from the north and south, are, in consequence of the earth's rotation on its axis, deflected from their course as they approach the equatorial region, and thus become north-east and south-east winds, constituting the trade-winds. The space included between the second and fifth degrees of north latitude, is the internal boundary of the trade winds; and this space experiences calms, frequently interrupted, however, by violent storms. The position of the sun has an influence on the strength and direction of the trade-winds; for when the sun is near the tropic of Cancer, the south-east wind becomes gradually more southerly and stronger, and the north-east weaker and more easterly; the effect is reversed when the sun approaches towards the tropic of Capricorn. Trade-winds are constant only over the open ocean, and the larger the expanse of ocean over which they blow, (as in the Pacific,) the more steady they are. When these winds blow over land, they are obstructed and their direction changed by coming in contact with high land or mountains. In some places the trade-winds become periodical, blowing one half of the year in one direction, and the other half in the opposite direction. [See MONSOON.]

colour is whitish or yellowish. Both sorts are hard, yet somewhat soft, and even flexible before breaking; the fracture dull and splintery. Tragacanth is devoid of taste or smell. It swells in the mouth, and is lubricous. It is composed of gum, bassorin, starch, and vegetable membrane, and is imperfectly soluble. A Greek tragedy always consisted of two distinct parts; the dialogue, which corresponded in its general features to the dramatical compositions of modern times; and the chorus, the whole tone of which was lyrical rather than dramatic, and which was meant to be sung while the dialogue was intended to be recited. The unity of time;—namely, that the duration of the action should not exceed twenty-four hours; and that of place,—namely, that the scene in which the events occur should be the same throughout, are modern inventions. *Eschylus* is called the father of *tragedy*.—2. **TRANSCENDENT'AL**, *a.* Supereminent; surpassing others; as *transcendental* being or qualities.—2. In the Kantian philosophy, pertaining to that which transcends or goes beyond the limits of actual experience. The term, however, as distinguished from *transcendent*, is applied to that which does not indeed originate from experience, but yet is connected with it, because it contains the grounds of the possibility of experience. "I call," says Kant, "all knowledge *transcendental*, which occupies itself not so much with objects as with the way of knowing these objects, as far as this is possible *a priori*. A system of such notions would be called *transcendental philosophy*, and would be the system of all the principles of pure reason;" or, as he says in another passage, "the pure, merely speculative reason from which the practical is separated."—In *math.*, a term applied to any equation, curve, or quantity which cannot be represented or defined by an algebraical equation of a finite number of terms, with numeral and determinate indexes. Transcendental quantities include all exponential, logarithmic, and trigonometrical lines, because there is no finite algebraical formulae by which these quantities can be expressed.—*Transcendental equation* is an equation into which transcendental quantities enter. But *transcendental* equations sometimes signify such differential equations as can only be integrated by means of some curve, logarithm, or infinite series.—*Transcendental curve* is such as cannot be defined by any algebraic equation, or of which, when it is expressed by an equation, one of the terms is a variable quantity.

**TRANSCENDENT'ALISM**, *n.* In the Kantian philosophy, the transcending or going beyond empiricism, and ascertaining *a priori*, the fundamental principles of human knowledge. But, according to Schelling and Hegel, who reject Kant's distinction between *transcendent* and *transcendental* ideas, transcendentalism is that which aims at a true knowledge of all things, material and immaterial, human and divine, so far as the mind is capable of knowing them. And in this sense the term *transcendentalism* is now most used. Sometimes it is also used for that which is vague and illusive in philosophy.

The passage of one heavenly body over the disc of a larger one. But the term is chiefly

## TRANSITIVE

restricted to the passage of the inferior planets, Mercury and Venus, over the sun's disc. The transits of Venus are of great importance in astronomy, as they afford the best means of determining the sun's parallax, and consequently the dimensions of the planetary system. These transits are of rare occurrence. The last one took place June 3, 1769, and the next will happen December 8, 1874. The transits of Mercury occur more frequently, but they are comparatively useless, from the difficulty of observation.

The instrument is susceptible of certain nice adjustments, so that the axis can be made perfectly horizontal, and at right angles to the plane of the meridian, in which plane the telescope must move. The principal use of the transit instrument is to determine the exact moment when a celestial body passes the meridian of the place of observation. [*See TRANSIT.*]

**TRANSI'TION**, *n.* (*transizh'on*.) [*L. transitio*.] 1. Passage from one place or state to another; change; as, the *transition* of the weather from hot to cold. Sudden *transitions* are sometimes attended with evil effects.

The term *transition*, however, is no longer applicable in its original signification; and, accordingly, modern geologists include within the tertiary series all kinds of stratified rocks, from the earliest slates, in which we find the first traces of animal and vegetable remains, to the termination of the great coal formation. [*See STRATA.*]

**TRANSI'TIONAL**, } *a.* Containing **TRANSI'TIONARY**, } or denoting transition.

In this sentence, the act of writing, performed by Cicero, the agent, terminates on letters, the object. All verbs not passive, may be arranged in two classes, *transitive* and *intransitive*. In *Eng.*, this division is correct and complete.

The motion of a single point considered by itself must always be that of translation. This is a property of glass, water, and air, which, when clear, admit the free passage of light. This property is supposed to arise from the disposition of the particles which compose the transparent body. No substance, however, can be said to be perfectly transparent; that is, there is no substance which does not intercept some part of the light incident upon it, and the transparency of a substance, as water and glass, diminishes as its thickness or depth increases. On the other hand, all bodies possess transparency in some degree; the most dense metals, as gold, when rendered very thin, transmit light. Transparency is opposed to *opacity* or *opacuity*.—2. If  $a + x = b + c$ ; then, by transposing  $a$ , we get  $x = b + c - a$ . If again  $x - a = b + c$ ; then, by transposing  $-a$ , we get  $x = b + c + a$ . On these steps a number of prisoners are placed, and all mounting the first step together, make it to descend by their weight, when they mount the next higher step, which descends in the same manner, and so on, causing the wheel to turn round, by *treading* on the steps in succession. They are assisted and supported in this labour by a horizontal rail which they lay hold of. The rotatory motion of the wheel thus produced, may be applied as the moving force for grinding corn, or in turning any other machinery.

TREASON, *n.* (tree'zn.) [Fr. *trahison*; Norm. *trahir*, to draw in, to betray, to commit treason, Fr. *trahir*, *L. traho*. See DRAW and DRAG.] In law, an overt or open act of compassing or devising the death of the king. But the term includes numerous acts and circumstances, which constructively and remotely, as well as immediately, affect the safety of the king's person; such as the violation of females of the royal family, levying war against the king in his realm, adherence to the king's enemies, counterfeiting the king's seals, the offence of slaying the chancellor or the judges; also, writings which import such compassings, or devices, attempts, or intentions, if published or shown to third persons, or words of advice, or persuasion, importing deliberation and design. There are no accessories to treason; all are held to be principals. The punishment for treason is, that the offender be drawn on a hurdle to the place of execution, and there hanged; that his head should be cut off; and the body divided into four quarters; but the king by warrant may dispense with all the immaterial parts of the punishment. The party attainted for treason forfeits all lands and property, and his heirs cannot take by any descent through him. Formerly treason used to be styled *high treason*, in contradistinction to what was termed *petty treason*, which was the killing of a master by his servant, a husband by his wife, but every offence which formerly amounted to petty treason is now deemed to be murder only, and not treason. In the United States, treason is confined to the actual levying of war against the United States, or in adhering to their enemies, giving them aid and comfort. TREASONABLE, *a.* (tree'znable.) **TREASURER, n.** (trezh'urer.) One who has the care of a treasure or treasury; an officer who receives the public money arising from taxes and duties or other sources of revenue, takes charge of the same, and disburses it upon orders drawn by the proper authority. Incorporated companies and private societies have also their *treasurers*.—*Lord high treasurer*, formerly the third great officer of the crown, who had under his charge and government all the king's revenue, which is kept in the Exchequer; but at present the duties of the lord high treasurer are discharged by commissioners entitled *lords of the treasury*. [See **TREASURY**.]—*Lord high treasurer of Scotland*, formerly an officer whose duty it was to examine and pass the accounts of the sheriffs, and others concerned in levying the revenues of the kingdom, to receive resignations of lands, and other subjects, and to revise, compound, and pass signatures, gifts of tatory, &c. In 1663, the lord high treasurer was declared president of the Court of Exchequer. In this case, the treasure becomes vested in the king by virtue of his prerogative; but if the owner is known or is ascertained after the treasure is found, the owner and not the king is entitled to it. In former ages, when persons were in the practice of burying their money, and other treasures in the earth, on account of the insecurity of property, *treasure-trove* became an important branch of

**TREATING, pp.** Hoarding; laying up for future use.

**TREASURY, n.** (trezh'ury.) A place or building in which stores of wealth are repositied; particularly, a place where the public revenues are deposited and kept, and where money is disbursed to defray the expenses of government.

—2. A department of government, which has control over the management, collection, and expenditure of the public revenue. The duties of this department are at present performed by a board of five lords commissioners, instead of a lord high treasurer, as in former times. The chief of these commissioners, or first lord of the treasury, is generally the prime minister for the time being; the other four junior lords have usually seats in parliament, as have also the two joint secretaries of the treasury. The other subordinate officers are a number of clerks, a receiver of fees, a keeper of the papers, a solicitor, a chamber keeper, messengers, house-keepers, extra clerks and extra messengers. The departments immediately under the control of the treasury, are the boards of customs, of excise, of stamps and taxes, and the post-office, the various officers in which are to a great extent appointed by the lords of the treasury. The chancellor of the Exchequer has the especial management of the revenue and expenditure of the nation, and when the prime minister or first lord of the treasury is a peer, the former takes the lead of the ministerial party in the house of commons, in which the seats occupied by that party are called the *treasury benches*. When the first lord of the treasury is a commoner, the offices of the prime minister and chancellor of the Exchequer are sometimes united in the same person.—3. A building appropriated for keeping public money; John viii. Also for keeping accounts of public money.—4. The officer or officers of the treasury department. [See No. 2.]—5. 2. An agreement, league, or contract between two or more nations or sovereigns, formally signed by commissioners properly authorized, and solemnly ratified by the several sovereigns or the supreme power of each state. Treaties are of various kinds, as, *treaties* for regulating commercial intercourse, *treaties* of alliance, offensive and defensive, *treaties* for hiring troops, *treaties* of peace, &c. In most monarchies, the power of making and ratifying treaties is vested in the sovereign; in republics, it is vested in the chief magistrate, senate, or executive council; in the United States of America it is vested in the president, by and with the consent of the senate; while in the Germanic confederation, the particular states have the right of making treaties of alliance and commerce not inconsistent with the fundamental laws of the confederation. The East India Company enjoys the right of making treaties under certain limitations; but in all cases treaties can only be made by the sovereign power in a state, or by

## TREBUCHET

parties upon whom the sovereign power has conferred that right. Hence, in order to enable a public minister or other diplomatic agent to conclude and sign a treaty, he must be furnished with full power by the sovereign authority, and the treaty concluded in this manner is binding on the state, in the same manner as if it had been concluded immediately by the sovereign power. In most constitutional governments it is necessary that the sanction of the legislative body be given to treaties of commerce, or those which impose taxes on the people, entered into by the executive.—3 † *Entreaty*. **TREATY-MAKING**, *a.* Authorized to make or form treaties; as, a *treaty-making power*.

**TREBLE**, *a.* (trib'l.) [Fr. *triple*; *L. triplex, triplus*; *tres*, three, and *plexus*, fold.] 1. Threefold; triple; as, a lofty tower with *treble walls*.—2. ## TREE-FROG

missiles into the towns and castles they beleaguered. The receptacle at the lower portion of the machine being filled with the missiles intended to be thrown, the upper arm of the instrument, loaded with a heavy weight, was allowed to descend, which, owing to the unequal balance, it did with great velocity; and the large arm then swung in the air, and scattered its contents.

It is not easy to ascertain the real original orthography; most probably it was as in the Swedish or Greek.] 1. A perennial plant having a woody trunk of varying size, from which spring a number of branches, having a structure similar to the trunk. Trees are thus distinguished from shrubs which have perennial stems, but have no trunk properly so called; and from herbs, whose stems live only a single year. It is difficult, however, to fix the exact limit between trees and shrubs. Trees, as to classification, may be either dicotyledonous or exogenous, monocotyledonous or endogenous, acotyledonous or acrogenous. [See these Terms.] Trees are of various kinds; as, *nuciferous*, or nut-bearing trees; *bacciferous*, or berry-bearing; *coniferous*, or cone-bearing, &c.; *standard trees*, *dwarf trees*, *wall trees*, &c. ated mouth. The ordinary length is about a span, and the girth two or three inches, although some are found two feet in length, and seven or eight inches in circumference.

When the trepan is taken, it is gutted, dipped for a short time in boiling water, then boiled in salt water for eight or ten hours, along with pieces of red mangrove bark, then dried and smoked over a wood fire, and this is all the preparation it receives. The fishery is carried on in numerous localities in the Indian ocean, the eastern Archipelago, and on the shores of Australia. The whole produce goes to China.

It consists of a cylindrical saw, with a handle placed transversely, like that of a gimlet, and has a sharp steel point, called the centre-pin, which may be fixed and removed at pleasure, and which stands in the centre of the circle formed by the saw, but projecting a little below the edge of the saw. The centre-pin is fixed in the skull, and forms an axis, round which the circular edge of the saw rotates, and as soon as the teeth of the saw have made a circular groove in which they can work steadily, the centre-pin is removed. The saw is made to cut through the bone, not by a series of complete rotations, such as are made by the trepan, but by rapid half rotations, alternately to the right and left, as in boring with an awl. The trephine is used especially in injuries of the head, and in cases resulting from injuries, for which the removal of a portion of the brain is necessary. The use of the trephine, however, is now much more rarely required than in former times, owing to improved modes of treating cases to which it was formerly applied, and the invention of simpler and more effective instruments.

trigonometry. [See TRIGONOMETRICAL.]

These lines have certain relations to each other, and numbers representing them, or the logarithms of such numbers, are formed into tables, for facilitating calculations in trigonometry.

— *Trigonometrical curves*, a name given to certain curves, which have such equations as  $y = \sin x$ ,  $y = \cos x$ ,  $y = a \cos x + b \cos 2x$ , &c. These curves may be constructed from the fundamental properties of the sine, cosine, &c. — *Trigonometrical series*, infinite series which are of the form  $a \sin x + b \sin 2x + c \sin 3x$ , &c., and  $a \cos x + b \cos 2x + c \cos 3x$ , &c.

— *Trigonometrical survey*, a term which may be applied to any survey of a country, which is carried on from a single base, by the computation of observed angular distances; but the term is usually confined to measurements on a large scale, embracing a considerable extent of country, and requiring a combination of astronomical and geodetical operations. A trigonometrical survey may be undertaken either to ascertain the exact situation of the different points of a country relatively to each other, and to the equator and meridians of the terrestrial globe, for the purpose of constructing an accurate map; or to determine the dimensions and form of the earth, by ascertaining the curvature of a given portion of its surface, or by measuring an arc of the meridian. The most minute accuracy and the most perfect instruments, are required in all the practical parts of such operations; and it becomes necessary to have regard to the curvature of the earth's surface, the effects of temperature, refraction, altitude above the level of the sea, and a multitude of circumstances, which are not taken into account in ordinary surveying. In conducting a trigonometrical survey of a country, signals, such as spires, towers, poles, erected on elevated situations, or other objects, are assumed at as great a distance as will admit of distinct and accurate observations, with telescopes of considerable power attached to the instruments used in measuring the angles. In this way the country will be divided into a series of *primary triangles*; and if any side of any one of these be measured, the remaining sides of all of them may be computed by trigonometry. By means exactly similar, each of these triangles is resolved into a number of others called *secondary triangles*; and thus the positions of towns and other remarkable objects are determined. The length of the base or line measured, which is an arc of a great circle, must be determined with extreme accuracy, as an error in measuring it would affect the entire survey. For checking the measurements and the computations, it is proper to measure some other line at a considerable distance from the first; as the comparison of its measured and computed lengths will be a test of the accuracy of the intermediate operations. Such a line is called a *base of verification*.

*tion*. The measurement of a base is one of the principal difficulties in the survey, chiefly on account of the inequalities of the earth's surface, and the variations in the length of the measuring instrument, arising from the change of temperature. The base is assumed on as flat a portion of country as can be obtained, and the chain or other measuring instrument is constructed with extreme care.

**TRIGONOMETRICALLY**, *adv.* According to the rules or principles of trigonometry.

**TRIGONOMETRY**, *n.* [Gr. *τρίγωνον*, a triangle, and *μετρέω*, to measure.] According to the primitive meaning of the term, the measuring of triangles, or the science of determining the sides and angles of triangles, by means of certain parts which are given; but in its modern acceptance it includes all theorems and formulae relative to angles and circular arcs, and the lines connected with them, these lines being expressed by numbers or ratios. In fact, the principles of trigonometry are of very general application, furnishing means of investigation in almost every branch of mathematics. Trigonometry, in relation to its practical utility, may be regarded as the most important of all the applications of mathematics, especially in relation to astronomy, navigation, and surveying. Trigonometry is of two kinds, *plane* and *spherical*, the former treating of triangles described on a plane; and the latter, of those described on the surface of a sphere. In every triangle there are six things which may be considered, viz., the three sides and the three angles, and the main object of the theoretical part of trigonometry is to deduce rules, by which, when some of these are given, the others may be found by computation, such computations being facilitated by tables of sines, tangents, &c. In plane trigonometry any three of the six parts of a triangle being given, (except the three angles,) the other parts may be determined; but in spherical trigonometry this exception has no place, for any three of the six parts being given, the rest may thence be determined, the sides being measured or estimated by degrees, minutes, &c., as well as the angles. Both plane and spherical trigonometry is divided into *right-angled* and *oblique-angled*.

1. Among the *ancient Romans*, a pompous ceremony performed in honour of a victorious general, and the highest military honour which he could obtain. It was granted by the senate only to a dictator, consul, or praetor, and after a decisive victory, or the complete subjugation of a province. In a Roman triumph, the general to whom this honour was awarded, entered the city of Rome in a chariot drawn by four horses, crowned with laurel, and having a sceptre in one hand, and a branch of laurel in the other. He was preceded by the senate and magistrates, musicians, the spoils, the captives in fetters, &c., and followed by his army on foot, in marching order. The procession advanced in this order along the *via sacra* to the capitol, where the general sacrificed a bull to Jupiter, and deposited his wreath in the lap of the god. Banquets and other entertainments concluded the solemnity, which was generally brought to a close in one day, though in later times it sometimes lasted for three days. During the time of the empire, the emperor himself was the only person that could claim a triumph. The *ovation* was an honour inferior to a triumph, and less imposing in its ceremonies.—2. event, or in honour of some victorious general. The Romans were the first people who erected triumphal arches. At first they were extremely plain and simple, but afterwards the style became enriched, and the whole was at length loaded with a profusion of every sort of ornament. Latterly, they were a rectangular mass penetrated by three arches, a central one, and two smaller side ones; as, the arches of Constantine, Septimius Severus, &c. In cases where they served as gates, they were usually constructed with two archways, one for carriages passing into the city, and the other for carriages passing out of it. Many beautiful structures, in imitation of the ancient triumphal arches, have been erected in modern times. In *modern times*, a temporary kind of triumphal arch is frequently, on festive occasions, formed of festoons of green branches, flowers, &c.—*Triumphal column*, among the Romans, an insulated column erected in commemoration of a conqueror, to whom had been decreed the honours of a triumph; as, the columns of Trajan and Antonine.—*Triumphal crown*, a crown usually awarded by the Romans to their victorious generals. sisting of three tubes; the first, to which the mouth-piece is attached, and the third, which terminates in a bell-shaped orifice, are placed side by side; the middle tube is doubled, and slides into the other two like the tube of a telescope. By the slide of the tube, every sound in the diatonic and chromatic scales being within its compass, is obtained in perfect tune, and thus the trombone surpasses every other instrument, in admitting, like the violin or the voice, the introduction of the slide. The trombone is of three kinds, the *alto*, the *tenor*, and the *bass*; and in orchestral music, these are generally used together, forming a complete harmony in themselves.

It consisted of some of the arms and other spoils of the vanquished enemy, hung upon the trunk of a tree, or a stone pillar, by the victorious army, either on the field of battle, or in the capital of the conquered nation. The custom of erecting trophies was most general among the Greeks, but it passed at length to the Romans. The Roman trophies, however, were usually constructed of more solid and durable materials than the Greek, such as towers, columns, &c. It was the practice, also, to have representations of trophies carved in stone, in bronze, and other solid substances. Many representations of trophies are to be found upon ancient medals, coins, &c.—2. Any thing taken and preserved as a memorial of victory, as arms, flags, standards, and the like, taken from an enemy.

**TROPIC**, *n.* [*Fr. tropique*; *L. tropicus*; from the Gr. *τροπος*, a turning; *τρομα*, to turn.].—1. In *astron.*, the tropics, or tropical circles, are two parallels of declination, whose distances from the equator are each equal to the obliquity of the ecliptic, or twenty-three degrees and a half nearly. The northern one passes through the point Cancer, and is thence called the tropic of Cancer, and the southern one, which passes through the point Capricorn, is called the tropic of Capricorn. The sun's annual path in the heavens is bounded by these two circles, and they are called tropics, because when the sun, in his journey northward or southward, reaches either of them, he, as it were, turns back, and travels in an opposite direction in regard to north and south. [See *ECLIPTIC SOLSTICE*.]—2. In *geography*, the tropics are two parallels of latitude, each at the same distance from the terrestrial equator as the celestial tropics are from the celestial equator. The one north of the equator is called the tropic of Cancer, and that south of the equator the tropic of Capricorn. Over these circles the sun is vertical when his declination is greatest, and they include that portion of the globe which is called the torrid zone.

The ostensible design of this system was to supply the workmen and their families with provisions, clothing of good quality, &c., at the cheapest rate, and thus to leave them but little money for the purposes of drinking and idleness. The truck system, however, was liable to great abuses. It gave rise to unfair dealing, and a species of tyranny; the workmen had often to pay exorbitant prices for their goods, and from the great facility afforded to them of procuring liberal supplies of goods in anticipation of wages, they were led into debt. These, and other evils incident to the truck system, induced the legislature to put a stop to it by an act passed in 1831.

It consists of a folded tube, generally of brass, but sometimes of silver, with a large bell-shaped aperture at one end for the emission of the sound, and a mouth piece at the other, adapted for blowing into the instrument with the mouth. The natural scale of the trumpet is limited, but by means of slides and keys, the number of notes may be greatly increased. It is the loudest of all portable wind instruments, and from its exciting effect, is well adapted for military music. It is used also for giving signals, and accompanies flags of truce, heralds, &c.

*Speaking trumpet*, an instrument for increasing the intensity of articulate sounds, and transmitting them to considerable distances in a particular direction. It is constructed of various forms, but usually consists of a tin or copper tube from six to twelve or more feet long, of such a form that its diameter becomes greater towards the extremity furthest from the mouth. The mouth piece is made large enough to admit both lips. Philosophers are not agreed as to the best form of the speaking trumpet, as the theory of the instrument is attended with considerable difficulty. The sound which the trumpet conveys in one direction is supposed to be increased not so much from its being prevented from spreading in all directions, as by repeated reflections of the sound from the sides

[See *USES*.] In *Scots* law, the term *trust* bears the same general signification as in English law, but in regard to the modes of constituting trusts, and the forms and technicalities connected therewith, the laws of the two kingdoms differ materially. For example, by the law of Scotland, a trust affecting heritage must be constituted by a formal disposition of the trustee, called a *trust-deed*, and completed by assent of the heritage; whereas by the law of England, trusts of a like kind are not required to be declared or created by writing, but only manifested and proved by writing, and the law is satisfied if the trust be manifested by any subsequent acknowledgment on the part of the trustee, however informal or indirect, as by a letter under his hand, his answer in Chancery, or by a recital in a deed, &c., and though the writing itself must be signed, the terms of the trust may be collected from a paper not signed, provided it can be clearly connected with the signed writing.

She said, *Truth*, Lord; yet the dogs eat of the crumbs; Matt. xv.

That is, it is a truth; what you have said, I admit to be true. According to Dr. Reid, the truths that fall within the compass of human knowledge, whether they be self-evident or deduced from those that are self-evident, may be reduced to two classes, namely, *necessary* and *immutable truths*, and *contingent* and *mutable truths*. A necessary truth is one that depends not upon the will and power of any being; it is immutably true, and its contrary impossible. A contingent truth is one which depends upon some effect of will and power, which had a beginning and may have an end. Of the first class are the axioms in mathematics, and all the conclusions drawn from them; that is, the whole body of the science of mathematics. Some first principles, also, belonging to other sciences, are necessary truths; such as the following:—That every proposition must either be true or false; that the qualities which we perceive by our senses must have a subject, which we call body; and that the thoughts we are conscious of must have a subject, which we call mind; and that, whatever begins to exist, must have a cause which produced it. To the second class of truths, viz., those that are contingent, belong the truths of natural philosophy, which depend upon the will of the Maker of the world, and also the principles from which they are deduced. In short, all those truths that express matters of fact or real existences, depending upon the will and power of the Supreme Being, are contingent, with exception of his own existence and nature, which is a necessary truth.—*First truths*, first or fundamental principles; intuitive articles of belief, which form the foundation of all reasoning.—*In truth*, in reality; in fact.—*Of a truth*, in reality; certainly.—*To do truth*, is to practice what God commands; John iii.

**TUMOUR**, *n.* [L. from *tumeo*, to swell.] 1. In *sur.*, a swelling; a morbid enlargement of any part of the body.

This is a word of very comprehensive signification, and it is very difficult to define exactly the diseases commonly classed under the name of *tumours*. According to some, a tumour is the

## TUMULTUARINESS

morbid enlargement of a particular part, without being caused by inflammation, a swelling which arises from inflammation being termed *tumefaction*. According to others, a tumour is any swelling which arises from the growth of distinct superfluous parts or substances, which did not make any part of the original structure of the body, or from a morbid increase in the bulk of other parts, which naturally and always existed in the human frame. The term *tumour* is limited, by Abernethy, to such swellings as arise from new productions, and includes only the *sarcomatous* and *encysted* tumours. An *encysted tumour* is one which is formed in a membrane called a *cyst*, connected with the surrounding parts by the neighbouring cellular substance. There are also fatty tumours, called *lipomatus* or *adipose* (*adipose sarcoma*), formed by an accumulation of fat in a limited extent of the cellular substance. Another division of tumours, considered as morbid parasitic growths, is into *malignant* and *innocent*. A *malignant tumour* is one which, after being removed by operation, is likely to recur in the same or some other part, while an *innocent tumour* is one which is not likely to recur after being removed by operation. Those tumours which are termed *tuberculous*, *medullary*, and *cancerous*, belong to the former class; and those termed the *common vascular*, the *adipose*, and the *pancreatic*, to the latter.—2. In the most ancient tumuli, bodies are found deposited within a stone receptacle, with the head towards the north. The bones which have been discovered within those tumuli which have been opened, are generally accompanied by utensils, weapons, &c. In some tumuli only have been found; in others, both bodies and urns, and in some the bones of animals. The tumuli found in this country are supposed to be of British construction. **TUNGSTATE**, *n.* A salt formed of tungstic acid and a base; as, tungstate of lime.

**TUNGSTEN**, *n.* [Sw. and Dan. *tung*, heavy, and *sten*, stone, heavy stone, or ponderous ore, so named from the density of its ores.] 1. A metal discovered by D'Elhnyart in 1781. It has a greyish white colour, and considerable lustre. It is brittle, nearly as hard as steel, and less fusible than manganese. Its specific gravity is 17.4. When heated to redness in the open air, it takes fire, and is converted into tungstic acid, and it undergoes the same change by the action of pitric acid. Digested with a concentrated solution of pure potash, it is dissolved with disengagement of hydrogen gas, and tungstate of potash is generated. The ores of this metal are the native tungstate of lime, and the tungstate of iron and manganese, which latter is also known by the name of Wolfram, and the same name is also given to the metal. Tungsten may be procured in the metallic state, by exposing tungstic acid to the action of charcoal or dry hydrogen gas at a red heat, but an exceedingly intense heat is required for fusing the metal. With oxygen, tungsten forms two compounds, the dark brown oxide, and the yellow acid of tungsten. With chlorine gas it forms two chlorides, a bichloride, and a tetrachloride. Both are red, volatile, and crystallizable compounds, subliming in beautiful crystals.—2. An obsolete name for the native tungstate of lime.

**TUNGSTENIC**, *† a.* Pertaining to or procured from tungsten.

**TUNGSTIC ACID**, *n.* An acid composed of one equivalent of the metal tungsten, and three equivalents of oxygen. It is obtained by heating the brown oxide of tungsten to redness in open vessels, and it may also be obtained from the native tungstate of lime, and from Wolfram. It is a yellow powder, insoluble in water. With bases it forms crystallizable salts. When exposed to the action of hydrogen gas at a temperature of 600° or 600°, it becomes of a fine deep blue, and is converted into the blue oxide of tungsten, which is regarded as a tungstate of tungsten.

**TUNGSTO SULPHURETS**. Compounds of tungsten and sulphur. They have no peculiar interest.

**TUNIC**, *n.* [Fr. *tunique*; L. *tunica*. See TOWN and TUN.] 1. A garment worn by the Romans of both sexes under the toga, and next to the skin. It was a kind of vest, generally of wool, of a white colour, and, as worn by men, came down a little below the knees before, and to the middle of the legs behind. It was fastened by a girdle or belt about the waist, to keep it tight when they went abroad, the girdle also serving as a purse, in which they kept their money. The tunic was at first worn without sleeves, but afterwards sleeves came to be used with fringes at the hands. The senators had a broad stripe of purple (called *latus clavus*) sewed on the breast of their tunic, and the equites had a narrow stripe (called *angustus clavus*) on the breast. Hence the terms *laticlavii* and *angusticlavii*, applied to persons of these orders. The tunic worn by women had sleeves, and reached down

**TUNING**, *n.* The art or operation of adjusting the various sounds of a musical instrument, so that they may be all at due intervals, and the scale of the instrument brought into as correct a state as possible. In tuning an instrument, the first point is to fix upon some one note as a leading note, and then by the pitch of it to determine the relative sounds of all the rest.—2. The art or operation of adjusting two or more musical instruments, so as to bring them into agreement with each other, as two or more violins, a violin and violoncello, &c. Horns, flutes, &c., have a permanent relative scale, and only change their pitch by change of temperature. [See **TEMPERAMENT**.]

The art of turning is of immense importance to the practical mechanic, and in the whole range of manufactures, whether of articles of necessity, utility, ornament, or luxury, there is no art so generally applied. At the same time, there is probably no art in the range of mechanical operation susceptible of greater accuracy, and there is none which has so much contributed to the improvement of machinery. The lathe is a most wonderful contrivance, especially when we take into account all the improvements it has undergone, from its simplest and most ancient form in the potter's wheel, to that adaptation of varied and complex mechanism, by which, not merely cir-

cular turning of the most beautiful and accurate description, but exquisite figure-work, and complicated geometrical designs, depending upon eccentric and cycloidal movements, are produced. In ordinary turning, the body operated upon is made to revolve on a stationary straight line, as an axis, and a cutting tool applied to its surface in such a way, as, in the circumvolutions of the object, to cut off those parts which lie farthest from the axis, and make the outside of the substance concentric with the axis. In this case any section of the work made at right angles to its axis will be of a circular figure; but there are methods of turning several other curves in a variety of ways. Lathes are made in a great variety of forms, and put in motion by different means. They are called *centre lathes*, when the work is supported at both ends; *mandrel*, *spindle*, or *chuck-lathes*, when the work is fixed only at one end. There are also *pole lathes*, and *turn-bench lathes*, which resemble each other; *foot-lathes*, which are moved by the foot; *bar-lathes*, &c. Lathes for great works are moved by horses and water-wheels, but more generally by steam-engines. In its wild state, it is a native of Great Britain, found in the borders of fields and waste places; but by cultivation the size of the plant, especially of the tuber or underground stem, is greatly increased. There are many varieties of the turnip cultivated for the table, and also in the fields. Those grown by farmers may be arranged as *whites* and *yellows*. The Swedish turnip is the *Brassica campestris rutabaga*. The young leaves and buds of the turnip are gathered and eaten under the name of *turnip tops*; the tubers consist of a large mass of soft cellular tissue, in which starch and sugar are deposited. The matrix is then placed in a mould, of which it forms the bottom, and into this mould is poured the type-metal in the requisite state of fluidity. The mould forms the body of the type, and consists of two halves, so that every letter which is cast may be easily loosened, and removed from it. A single type consists of three parts; the *shank*, or body of the letter, the *head*, or that part between the shoulder of the shank and the face, and the *face* or shape of the letter from which the impression is to be taken. The place where types are made is called a *type-foundery*.

# U.

**U** is the twenty-first letter and the fifth vowel in the English Alphabet. Its true primary sound in Anglo-Saxon, was the sound which it still retains in most of the languages of Europe; that of *oo* in *cool*, *tool*, answering to the French *ou*, in *tour*. This sound was changed, probably under the Norman kings, by the attempt made to introduce the Norman French language into

common use. However this fact may be, the first, or long and proper sound of *u*, in English, is now not perfectly simple, and it cannot be strictly called a *vowel*. The sound seems to be nearly that of *eu*, shortened and blended. This sound, however, is not precisely that of *eu* or *yu*, except in a few words, as in *unite*, *union*, *uniform*; the sound does not begin with the distinct sound

of *e*, nor end in the distinct sound of *oo*, unless when prolonged. It cannot be well expressed in letters. This sound is heard in *annuity*, *numerate*, *mute*, *dispute*, *duke*, *opportunity*, *infusion*. Some modern writers make a distinction between the sound of *u*, when it follows *r*, as in *rude*, *truth*, and its sound when it follows other letters, as in *mute*, *duke*; making the former

sound equivalent to *oo*; *rood*, *trooth*; and the latter a diphthong equivalent to *eu* or *yu*. The difference, very nice indeed, between the sound of *u* in *mute*, and in *rude*, is owing entirely to the articulation which precedes that letter. For example, when a labial, as *m* or *p*, precedes *u*, we enter on its sound with the lips closed, and in opening them to the position required for uttering *u*, there is almost necessarily a slight sound of *e* formed before we arrive at the proper sound of *u*. When *r* precedes *u*, the mouth is open before the sound of *u* is commenced. [See INTRODUCTION, p. lii.] In some words, as in *bull*, *full*, *pull*, the sound of *u* is that of the Italian *u*, the French *ou*, but shortened. This is a vowel. *U* has another short sound, as in *tun*, *run*, *sun*, *turn*, *rub*. This also is a vowel. *U* and *V* were long used indiscriminately, the one for the other, but since the beginning of the 16th century they have been separated, *U* being considered as a vowel, and *V* a consonant. In abbreviations, *U. S.* stand for *United States*; *ult.* for *ultima*, in the last month being understood. As a Latin abbreviation, *U. C.* stand for *Urbe condita*, the city having been built, that is Rome: thus *U. C.* 400 signifies 400 years after the building of Rome.

## ULTRAMARINE

carbonate of potash is separated into carbonic acid and potash; but when the operation is extended, and the carbonic acid is resolved into carbon and oxygen, and the potash into potassium and oxygen, the analysis is ultimate; for neither carbon, oxygen, nor potassium is resolvable into two or more kinds of matter; they are therefore to be considered as *ultimate elements*, or constituents. The terms *ultimate analysis*, and *ultimate elements*, are most generally used in reference to organic products. In inorganic analysis, the proximate elements are the substances generally sought, and the elementary composition of these being already known, the ultimate elements of which the substance analyzed is composed are also ascertained.—*Prime and ultimate ratios.* [See under *RATIO*.]

They are herbs, seldom shrubs, with fistular furrowed stems. The leaves are in most cases divided; they are alternate, and all of them embrace or clasp the stem by a sheathing petiole. The flowers are white, pink, yellow, or blue, and are seated on umbels which are either simple or compound. The fruit consists of two carpels united by a common axis. The seed is pendulous, and contains a large quantity of albumen in proportion to the size of the embryo. The genera are very numerous, and the species extremely so, and difficult to recognize. ## UNEASINESS

sometimes called *vibratory*; but *undulatory* seems to be most correct.—*Undulatory theory*, in *optics*, the hypothesis, according to which the phenomena of light are explained by the supposed vibrations or undulations of an ethereal medium, set in motion by the luminous body. This theory is opposed to the *theory of emanations*, or, as it is sometimes called, the *emission theory*, or *material theory*, according to which light is a material fluid of extreme subtilty. According to the former theory, the universe is filled with an ether or medium of great elasticity and rarity, which transmits light in the same manner as air transmits sound, and the impression is conveyed from the luminous body to the eye by successive undulations of this medium, occasioned by the luminous body; according to the latter theory, the luminous body constantly throws off material particles in every direction, which proceed in straight lines, and these particles falling upon the eye produce vision. Neither the undulatory nor material theory can be said to be satisfactorily established; but it would seem that every phenomenon which can be brought under the latter, can also, with equal facility, be explained by the former; while there are some known effects, as the phenomena of inflexion, in strict accordance with the former, which cannot, without great difficulty, and the introduction of gratuitous suppositions, be accounted for by the latter. Hence the undulatory theory has been more generally adopted in the investigations of modern philosophers.

One kingdom, joy and *union* without end.  
*Milton.*

2. Concord; agreement and conjunction.

States united. Thus the United States of America are sometimes called the *Union*.—8. A pearl. [L. *unio*.]—*Union flag*, in the navy, one of the three ensigns or standards in which the crosses of St. George, St. Andrew, and St. Patrick are blended, to denote the union of the three kingdoms. This flag is appropriated to the admiral of the fleet, who is the first naval officer under the lord high admiral.—*Union jack*. **UNISON**, *n.* [*L.* *unus*, one, and *sonus*, sound.] 1. In *music*, an accordance or coincidence of sounds proceeding from an equality in the number of vibrations made in a given time by a sonorous body. If two chords of the same matter have equal length, thickness, and tension, they are said to be in *unison*, and their sounds will be in *unison*. Sounds of very different qualities and force may be in *unison*; as, the sound of a bell may be in *unison* with a sound of a flute. *Unison* then consists in sameness of degree, or similarity in respect to gravity or acuteness, and is applicable to any sound, whether of instruments or of the human organs, &c.—2. A single unvaried note.—*In unison*, in agreement; in harmony.

**UNIT**, *n.* [*L.* *unus*, one; *unitas*, unity.]

1. One; a word which denotes a single thing or person.—2. In *arith.*, the least whole number, or one, represented by the figure 1. Every other number is an assemblage of units. This definition is applicable to fractions as well as to whole numbers. Thus, the fraction  $\frac{7}{10}$  is an assemblage of seven units, each of which is one-tenth of the integer.

Units are the integral parts of any large number. *Watts.*

3. In *math.*, any known determinate quantity, by the constant repetition of which, any other quantity of the same kind is measured; or it is the name given to that magnitude, which is to be considered or reckoned as one, when other magnitudes of the same kind are to be measured. It is not itself one, but is the magnitude which one or 1 shall stand for in calculation: it is a length, or a surface, or a solid, or a weight, or a time, as the case may be, while 1 is only a numerical symbol. This symbol 1 represents the abstract conception of singleness, as distinguished from multitude, and is the unit of abstract arithmetic: but all concrete quantities must have units of their own kind.—*Measuring unit*, in *mensuration*, a certain dimension or magnitude, assumed as a standard by which other dimensions or magnitudes of the same kind are to be measured.

## UNITE

Thus, in mensuration of surfaces, the measuring unit is a square inch, a square foot, a square yard, &c., and the area or superficies of any figure is estimated by the number of squares of this kind that are contained in it. In solids, the measuring unit is a cubical inch, a cubical foot, a cubical yard, &c., and the content or solidity of any figure is estimated by the number of cubes of this kind which it contains. In like manner, in lineal measure, the measuring unit is an inch, a foot, a yard, &c.—*Unit of time*, in *theoretical mech.*, one second, and all motion is measured by the space which is, or would be, passed over in this time; hence the velocity of a body signifies the space which it passes over in one second, and where one body is said to have a greater or a less velocity than another, it is meant that a greater or less space is passed over by it in one second.—*Unit of force or of weight*, in *theoretical mech.*, a certain force or weight assumed as a standard, by which other forces or weights, or their effects, may be estimated. This unit may be an ounce, a pound, a hundredweight, &c. [*See* **UNIT**.]

**UNITABLE**, *a.* Capable of being united.

**UNITARIAN**, *n.* [*L.* *unitas*, unity.] The Unitarians are a sect of religionists who confine the glory and attribute of divinity to the one only great and supreme God, and Father of our Lord Jesus Christ. The Unitarians are opposed to the Trinitarians, or those who conceive of one God in three persons, characters, or relations, each of which they regard as the proper object of religious worship. The Unitarian Christian believes the Father to be the only true God, and Jesus, his messenger, to be the Christ. This is the leading fundamental principle, which constitutes the true and complete definition of the term Unitarian; under which are consequently included all those who, receiving the divine authority or commission of Jesus Christ, believe him to be a dependent creature, deriving his existence from the Father, and therefore the fit object of all the veneration, submission, and obedience which can be offered to a creature, but not of religious worship, properly so called. Agreeing in this great and leading principle, Unitarians differ in their opinions as to the origin, nature, and dignity of Jesus Christ. One division of them has received the name of Arians, another that of Socinians.

**UNITARIAN**, *a.* Pertaining to Unitarians.

**UNITARIANISM**, *n.* The doctrines of Unitarians, who deny the divinity of Christ.

**UNITARIANIZE**, *v. t. and i.* To conform to Unitarianism.

**UNITE**, *v. t.* [*L.* *unio*, *unitus*; *Fr.* and *Sp.* *unir*; *It.* *unire*.] 1. To put together or join two or more things, which make one compound or mixture. Thus we unite the parts of a building to make one structure. The kingdoms of England, Scotland, and Ireland united, form one empire. So we unite spirit and water and other liquors. We unite strands to make a rope. The states of North America united, form one nation.—2. To join; to connect in a near relation or alliance; as, to unite families by marriage; to unite nations by treaty.—3. To make to agree or be uniform; as, to unite a kingdom in one

form of worship; to unite men in opinions.—4. To cause to adhere; as, to unite bricks or stones by cement.—

5. To join in interest or fellowship;

Gen. xlix.—6. To tie; to splice; as, to unite two cords or ropes.—7. To join

in affection; to make near; as, to unite hearts in love.

[*Unite* is followed by *to* or *with*. To unite *to*, is to join;

Gen. xlix. 6. To unite *with*, is to

associate; but the distinction is not

always obvious or important.]—To

unite the heart, to cause all its powers

and affections to join with order and

delight in the same objects; Ps. lxxxvi.

**UNITE**, *v. i.* To join in an act; to concur;

to act in concert. All parties united

in petitioning for a repeal of the law.

—2. To condescend; to be cemented or

consolidated; to combine; as, bodies

grow together, as the parts of a wound.

The spur of a young cock grafted into

the comb, will unite and grow. *Duhamel.*

4. To coalesce, as sounds.—5. To be

mixed. Oil and water will not unite.

**UNITED**, *pp.* Joined; made to agree;

cemented; mixed; attached by growth.

stamens and pistils in the same flower.

—*United brethren*, a religious com-

munity commonly called Moravians,

from their original country, Moravia,

where they sprung up on the first

opening of the Reformation. Generally

speaking, they adhere to the confession

of Augsburg, considering it as founded

on the Scriptures, which are the only

rule of their faith and practice. The

Moravians are remarkable for a meek,

quiet, and child-like spirit, and for

their earnest and unremitting labours in

attempting to convert the heathen.

**UNITEDLY**, *adv.* With union or joint

efforts.

**UNITER**, *n.* The person or thing that

unites.

**UNITING**, *ppr.* Joining; causing to

agree; consolidating; condescending; grow-

ing together.

**UNITION**, *n.* Junction; act of unit-

ing.

**UNITIVE**, *n.* Having the power of

uniting.

**UNIT JAR**, *n.* In *electrical experi-*

*ments*, a small insulated Leyden jar,

placed between the electrical machine

and a larger jar or battery. On work-

ing the machine, the small jar will

make repeated discharges, and these

will pass into the larger jar or battery.

Hence the use of this jar is to an-

ounce the number of such discharges,

from which an estimate may be formed

of the amount of electricity which

passes into the larger jar or battery.

**UNITY**, *n.* [*L.* *unitas*.] 1. The state of

being one; oneness. *Unity* may con-

sist of a simple substance or existing

being, as the soul; but usually it con-

sists in a close junction of particles or

parts, constituting a body detached from

other bodies. *Unity* is a thing undi-

vided itself, but separate from every

other thing.—2. Concord; conjunction;

as, a unity of proofs.—3. Agreement;

uniformity; as, unity of doctrine; unity

of worship in a church.—4. In *Chris-*

*tian theol.*, oneness of sentiment, affec-

tion, or behaviour.

How good and how pleasant it is for

brethren to dwell together in unity? Ps.

cxxxiii.

5. In *math.*, the abstract expression

for any unit whatsoever. The terms

unit and unity are often used synony-

## UNIVERSAL

mously, but in general, the number 1 is unity when it is not applied to any particular object; and a unit, when it is so applied. [See UNIT, No. 3.]—6. In poetry, the principle by which a uniform tenor of story and propriety of representation is preserved. In the Greek drama, the three unities required were those of action, of time, and of place; in other words, that there should be but one main plot; that the time supposed should not exceed twenty-four hours, and that the place of the action before the spectators should be one and the same throughout the piece. In the epic poem, the great and almost only unity is that of action.—7. In music, such a combination of parts as to constitute a whole, or a kind of symmetry of style and character.—8. In all the arts, the correspondence of the various parts of a work, so that they may form one harmonious whole. Unity is indispensable in every work of art.—9. In law, the properties of a joint estate are derived from its unity, which is fourfold; unity of interest, unity of title, unity of time, and unity of possession; in other words, joint-tenants have one and the same interest, accruing by one and the same conveyance, commencing at the same time, and held by one and the same undivided possession.—10. In law, unity of possession is a joint possession of two rights by several titles, as when a man has a lease of land upon a certain rent, and afterward buys the fee simple. This is a unity of possession, by which the lease is extinguished.—Unity of faith, is an equal belief of the same truths of God, and possession of the grace of faith in like form and degree.—Unity of spirit, is the oneness which subsists between Christ and his saints, by which the same spirit dwells in both, and both have the same disposition and aims; and it is the oneness of Christians among themselves, united under the same head, having the same spirit dwelling in them, and possessing the same graces, faith, love, hope, &c.

**UNIVALVE**, *a.* [L. *unus*, one and *valve*.] Having one valve only, as a shell or pericarp.

**UNIVALVE**, *n.* A shell having one valve only. The *univalves* form one of the three divisions into which shells were divided by Linnaeus, the other two divisions being bivalves and multivalves. In this arrangement the generic characters reside in the shell and not in the structure of the inhabiting animal. Modern naturalists have adopted a much more scientific system of arrangement in regard to testaceous or molluscous animals. Lamarck divides the bivalves into five orders, viz., Heteropoda, Cephalopoda, Trachelipoda, Gasteropoda, and Pteropoda. Univalves are far more numerous than either multivalves or bivalves, both in genera and species.

**UNIVALVED**, *a.* Having only one valve.

**UNIVALVULAR**, *a.* Having one valve only; as, a univalvular pericarp or shell.

**UNIVERSAL**, *a.* [L. *universalis*; *unus* and *versor*.] 1. All; extending to or comprehending the whole number, quantity, or space; as, universal ruin; universal good; universal benevolence.

The universal cause,

Acts not by partial, but by general laws.

## UNIVERSALNESS

2. Total; whole.

From harmony, from heav'nly harmony, This universal frame began. Dryden.

3. Comprising all the particulars; as, universal kinds.—4. In bot., a universal umbel, is a primary or general umbel; the first or largest set of rays in a compound umbel; opposed to *partial*. A universal involucre is not unfrequently placed at the foot of a universal umbel.—Universal dial, is a dial by which the hour may be found by the sun in any part of the world, or under any elevation of the pole.—Universal successor, in Scots law, an heir who succeeds to the whole of the heritage of a person who dies intestate.—Universal joint. [See JOINT.]—Universal proposition, one in which the subject is taken in its widest extent, and the predicate applies to every thing which the subject can denote. Thus, "all men are mortal," is a universal proposition, and also, "no man is perfect." A universal proposition is opposed to a particular proposition, or one which makes such an assertion or denial of some of the things spoken of, as implies that others are left unspoken of: Thus, "some men are born in England," and "some animals cannot live in this climate," are particular propositions. [See the Noun.]

**UNIVERSAL**, *n.* [See the Adjective.] In logic, a universal is complex or incomplex. A complex universal, is either a universal proposition, as "every whole is greater than its parts," or whatever raises a manifold conception in the mind, as the definition of a reasonable animal. An incomplex universal, is what produces one conception only in the mind, and is a simple thing respecting many; as human nature, which relates to every individual in which it is found.—2.† The whole; the general system of the universe.—Universals, the name given by the schoolmen to general notions or ideas, especially those of genera and species.

**UNIVERSALISM**, *n.* In theol., the doctrine or belief that all men will be saved or made happy in a future life.

**UNIVERSALIST**, *n.* One who holds the doctrine that all men will be saved, in opposition to the doctrine of eternal punishment. The universalists maintain that Christ died for all, and hence that all shall finally be brought to a participation of the benefits of his death, in their restoration to holiness and happiness. The name *universalists* is sometimes applied to the Arminians, in consequence of the *universality* which they ascribe to the operation of divine grace, and their opposition to the doctrine of *particular* election.

**UNIVERSALITY**, *n.* The state of extending to the whole; as, the *universality* of a proposition; the *universality* of sin; the *universality* of the deluge.

**UNIVERSALIZE**, *v. t.* To make universal.

**UNIVERSALIZED**, *pp.* Rendered universal.

**UNIVERSALIZING**, *ppr.* Rendering universal.

**UNIVERSALLY**, *adv.* With extension to the whole; in a manner to comprehend all; without exception. Air is a fluid universally diffused. God's laws are universally binding on his creatures.

**UNIVERSALNESS**, *n.* Universality.

Note.—Universal and its derivatives are used in common discourse for ge-

*neral*. This kind of universality is by the schoolmen called *moral*, as admitting of some exceptions, in distinction from *metaphysical*, which precludes all exceptions.

**UNIVERSE**, *n.* [Fr. *univers*; L. *universum*.] The general system of things; the collective name of heaven and earth, and all that belongs to them; the whole system of created things; the *kosmos* of the Greeks, and the *mundus* of the Latins.

**UNIVERSITY**, *n.* [L. *universitas*, the whole of any thing as contrasted with its parts; a community, association, corporation, company, &c.] In the modern sense of the term, an establishment or corporation for the purposes of instruction in all or some of the most important divisions of science and literature, and having the power of conferring certain honorary dignities, termed degrees. The term *university*, like many other terms of extensive application, has undergone various modifications of meaning, till its origin and primary use seem to have been utterly forgotten. In its proper and original meaning, it denotes the whole members of an incorporated body of persons, teaching and learning one or more departments of knowledge. In the technical language of the civil law, the word *universitas* was used to signify a plurality of persons, associated for a continued purpose, and may be rendered by *society*, *company*, *corporation*. In the middle ages, the term was used in reference to seminaries of learning, to denote either the whole body of teachers and learners, or the whole body of learners, with corporate rights and under bye-laws of their own, divided either by faculty or by country, or both together; its meaning being determined by the words with which it was connected. At a later period, the expression *universitas literarum* was used to indicate that all the most important branches of science were to be taught in these establishments; but although it is true that most of the modern universities embrace the whole circle of learning, as contained in the four faculties of the arts, theology, law, and physic, this was not the case in the 12th century, when the term *universities* was first applied to academical institutions. The university of Paris, as well as Oxford and Cambridge, existed at first only in the faculty of arts, and Salerno and Montpellier contained the single faculty of medicine. Some, forming their notion of the word *university* merely from the English universities, suppose that it necessarily means a collection and union of colleges; that it is a great corporation embodying in one the smaller and subordinate collegiate bodies; but this is not correct, for many universities exist in which there are no colleges. This is the case with most of the German universities, and in the Scottish universities there are no foundations which bear any resemblance to the English colleges; and, besides, the universities of Oxford and Cambridge existed before a single college was endowed. The oldest of the European universities were those of Paris and Bologna, and these formed the models on which the other universities, which subsequently sprung up in various parts of Europe, were established.
